Abstract

A duality formula, of the Hardy and Littlewood type for multidimensional Gaussian sums, is proved in order to estimate the asymptotic long time behavior of distribution of Birkhoff sums S_n of a sequence generated by a skew product dynamical system on the $\mathbb{T}^2$ torus, with zero Lyapounov exponents. The sequence, taking the values ± 1, is pairwise independent (but not independent) ergodic sequence with infinite range dependence. The model corresponds to the motion of a particle on an infinite cylinder, hopping backward and forward along its axis, with a transversal acceleration parameter α. We show that when the parameter α/π is rational then all the moments of the normalized sums $E\left((S_n/\sqrt{n})^k\right)$, but the second, are unbounded with respect to n, while for irrational α/π, with bounded continuous fraction representation, all these moments are finite and bounded with respect to n.

1 Introduction

Diffusion processes are the most important transport processes to be modelled in the frame of dynamical systems. For a particle having deterministic "chaotic" motion, diffusion appears in the long-time limit of the displacement governed by the dynamics under invariant probability measure. The extension of the Central Limit Theorem to deterministic dynamical systems is well established for many strongly chaotic systems. In these systems diffusion is related to strong mixing properties of the motion of the particles. However, this condition is sufficient, but not necessary.

A stationary bounded sequence of identically distributed random variables $X_0, X_1, \ldots,$ with zero mean value is ergodic if:

$$\frac{1}{n}\sum_{i=0}^{n-1} X_i \underset{n\to\infty}{\longmapsto} E(X_0) = 0 \tag{1.0.1}$$

It fulfills the Central Limit Theorem if there exists a positive sequence f_n such that $\frac{1}{f_n}\sum_{i=0}^{n-1} X_i$ converges in law to a normal centered distribution with variance 1. The validity of the Central Limit Theorem goes beyond the case of independent (Bernoulli) sequences X_i. Recently this problem has been cast in the more general setting of ergodic dynamical systems.

Let T be a measurable transformation on a space $\mathcal{X}$, equipped with a probability measure μ on a σ-algebra $\mathcal{F}$ of measurable sets. The measure μ is supposed to be T-invariant: for all A of $\mathcal{F}$ one has $\mu(T^{-1}A) = \mu(A)$. The system is also assumed to be ergodic:

$$\forall f \in \mathcal{L}^1(\mathcal{X}); \quad \frac{1}{n}\sum_{i=0}^{n-1} f(T^n X) \underset{n\to\infty}{\longmapsto} \int_X f(x)d\mu(x) = E(f) \tag{1.0.2}$$

almost everywhere. The sum:

$$S_n f(X) = \sum_{i=0}^{n-1} f(T^n X)$$

is called a **Birkhoff sum**. A real square-integrable function f, with zero mean value, is said to satisfy the Central Limit Theorem if:

$$\lim_{n\to\infty} \mu\left(X : \frac{1}{\sqrt{< S_n^2 >}}\sum_{i=0}^{n-1} f(T^n X) \in I\right) = \frac{1}{\sqrt{2\pi}}\int_I \exp(-\frac{x^2}{2})dx \tag{1.0.3}$$

In other words, the sum $\frac{1}{\sqrt{(<S_n f>)^2}} \sum_{i=0}^{n-1} f \circ T^n$ converges in law to a Gaussian variable of zero mean value and variance 1. A generalization of the Central Limit Theorem has been established for a class of regular functions for K-systems [Go], and for hyperbolic dynamical systems the auto-correlations of which decrease exponentially (see a review in [Li]). One of the most remarkable results of the theory of chaotic dynamical systems was the convergence of normalized Birkhoff sums of observables to a diffusion process. In the Lorentz gas, Bunimovich, Chernov, Sinai [BCS], [BS] and Young [CYo] have proved such behavior. They found a class of functions f for wich the rescaled ergodic sums converge to the Wiener process, i.e.

$$\sqrt{\tau} \sum_{n=0}^{[t/\tau]} f \circ T^n \underset{\tau \to 0}{\to} Y_t \tag{1.0.4}$$

where $t \in [0,1]$ and Y_t is a Brownian motion (other informations can be found in [Bi]). In non integrable area preserving maps numerical results on diffusion have been obtained by many authors (see, for instance, references in [Za], [MMP]). However to our knowledge, in the hamiltonian dynamical systems no rigourous proofs have been given. In [Za], there are several numerical evidences of the existence of anomalous transport in hamiltonian non integrable systems on account of the existence of islands into islands in the phase space of the systems due to the abundance of some stable periodic behaviors generating Levy flights. One of the main motivation of our work is to investigate diffusive behavior in simple ergodic area-preserving mappings with weakly chaotic properties (i.e. randomness with zero Lyapounov exponenets [CH3]). In such systems, the problem is to find a class of functions f for wich the rescaled ergodic sums converge to the Wiener process. A first step toward such result is to estimate the asymptotic behavior of the Birkhoff sums. In this work we consider this problem for completely non-hyperbolic systems having nevertheless a family of observables for which the two-times auto-correlations are zero. Swante Janson [J] has studied examples of non-ergodic stationary sequences with zero mean value and variance σ, such that the sequence $S_n = \sum_{i=0}^{n-1} X_i$ converges in law, without normalization, which implies a breaking of the Central Limit Theorem.

We shall consider an ergodic sequence of pairwise independent variables, each of them taking values in $\{-1, 1\}$ and having variance $\sigma^2 = 1$. They are derived from a dynamical system on the torus $\mathbb{T}^2$, called the Anzaï skew product and defined by:

$$T(x,y) \equiv (x+\alpha, y+x) \mod 2\pi \tag{1.0.5}$$

When α/π is irrational, Furstenberg (see ref. in [CFS]) has shown that this transformation has a unique invariant measure, which is thus ergodic and is in fact the normalized Lebesgue measure $\frac{dxdy}{(2\pi)^2}$. In a previous work [CH1] and [CH2] have determined partitions $\{A, A^C\}$, which are pairwise independent: $\mu(A \cap T^{-n}A) = \mu(A)^2$. It is equivalent to say that for the function $f = \mathbb{I}_A - \mu(A)$ the family of functions $f \circ T^n$ are pairwise independent random variables. However, this does not imply at all that these variables are jointly independant. Actually, the process has infinite memory because its metric entropy is zero, moreover, there is only linear divergence of trajectories. It is to be noted that on account of the pairwise independence, it can be immediately seen that the "diffusion coefficient" σ defined by:

$$\frac{1}{n}\int_I (\sum_{i=0}^{n-1} f(T^n x))^2 dx \underset{n\to\infty}{\longmapsto} \sigma^2$$

is finite. However, the existence of the diffusion coefficient is not sufficient to imply asymptotic normal distribution.

Thus it would be interesting to see whether the Central Limit Theorem holds here or not. We shall see that the result depends essentially on the continued fraction representation of α. In this work, A will be limited to the subset $\mathbb{T} \times [0,\pi]$, $X_i = f \circ T^i$ and the moments $E((S_n^q))$ will be asymptotically estimated. It is however difficult to reconstruct the characteristic function $\Phi_n(t)$ of $\frac{S_n}{\sqrt{n}}$. For odd q, $E(S_n^q) = 0$. For even q several situations can occur: We shall show that:

a) If α/π is an irrational number with a bounded continued fraction representation, then $E((S_n^{2q}) = \mathcal{O}(n^q)$. Consequently $\mid E((\frac{S_n}{\sqrt{n}})^{2q}) \mid \leq A_q$, where A_q is a constant. The convergence of the characteristic function depends on the A_q.

b) If α/π is an irrational but not of the previous type, then there is no f_n such that $E((\frac{S_n}{f_n})^{2k}) = \mathcal{O}(1)$, different from zero for all $k \geq 0$.

It is to be noted that our mapping gives interesting examples where the existence of th diffusion coefficient $\sigma^2 = \lim_{n\to\infty} E(S_n^2)/n = 1$ is not sufficient to imply the convergence to the normal distribution.

So it may be suggestive to start out with a concrete picture of particle dynamics. The dynamical system Eq. 1.0.5 corresponds to the motion of a rotator kicked at regular time interval by a force modulated so that the angular velocity remains bounded. Let $\theta(t)$ and $\dot{\theta}(t)$ be the angle and the angular velocity of the rotator, where $\dot{\theta}(t) \in [0, 2\pi[$. Then, at time $t+1$, the state of the rotator is given by

$$\begin{aligned} \theta(t+1) &\equiv \theta(t) + \dot{\theta}(t) \mod (2\pi) \\ \dot{\theta}(t+1) &\equiv \dot{\theta}(t) + \alpha \mod (2\pi) \end{aligned} \qquad (1.0.6)$$

and we have at time t:

$$\theta(t) \equiv \theta(0) + t\dot{\theta}(0) + \frac{t(t-1)\alpha}{2} \mod (2\pi) \qquad (1.0.7)$$

An idea of the randomness of this motion can be seen by using a partition $\{A, A^C\}$ of the torus into two regions: $A = \{\theta \in [0, \pi[\}$ and $A^C = \{\theta \in [\pi, 2\pi[\}$. It can be seen that:

$$\mu(A_i \cap T^{-n} A_j) = \mu(A_i)\mu(A_j)$$

for any $n \neq 0$, where A_i is either A or A^c [CH1]. This partition is far from being a Bernoulli one since the entropy of the system is zero. We call such partitions pairwise independent. In [CH3], it is shown that such sequences are unpredictable in the sense of Wiener least squares criterion. It is natural to study the distributions of sums of such sequences, which represent a particle displacement induced by the dynamical system of the Eq. (1.0.5) as follows.

A particle moves on an infinite plane among periodically distributed obstacles with spatial period equal to 1 along both (q_1, q_2)-directions. In the q_1-direction, the motion of the particle is uniformly accelerated at each regular time interval by an amount α and has uniform free motion along the q_2-direction. That is, define the velocity $p_1(n) = q_1(n+1) - q_1(n)$, then the equations of the projection of the motion in the q_1-direction are :

$$q_1(n) = q_1(n-1) + p_1(n-1) \qquad (1.0.8)$$

$$p_1(n) = p_1(n-1) + \alpha \qquad (1.0.9)$$

It is the result of the discrete time action of the mapping: $T : (p_1, q_1) \to T(p_1, q_1)$ given by:

$$T(p_1, q_1) = (p_1 + \alpha, q_1 + p_1) \qquad (1.0.10)$$

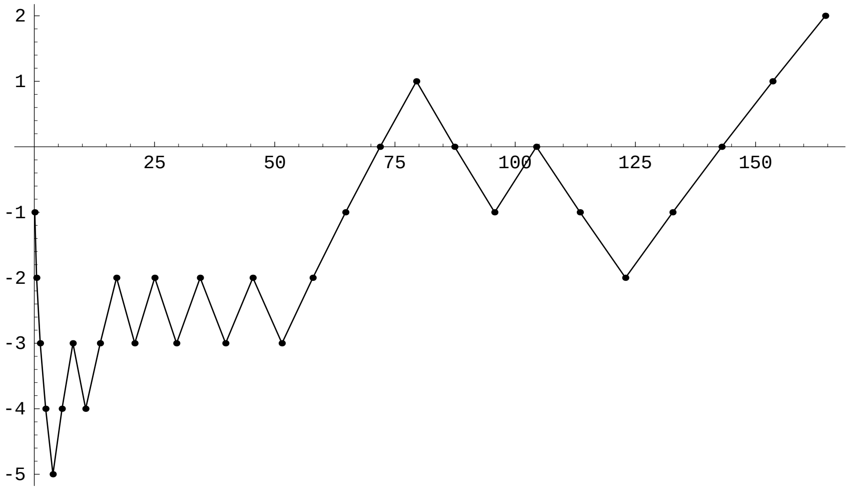

Figure 1: Trajectory of the particle in the plane (q_1, q_2).

Thus, we obtain:

$$q_1(n) = q_1(0) + np_1(0) + n(n-1)\alpha/2 \tag{1.0.11}$$

The particle is moreover submitted at the begining of each time interval to a field changing the direction of the motion up and down along q_2-direction in terms of its position along the q_1-direction in the following way (see figure 1): the velocity direction of the particle p_2 at time $t = n$ is given by $\chi(q_1(n))$ where $\chi(x)$ is a periodic discontinuous function defined by:

$$\chi(x) = \begin{cases} -1 & if \quad x \in]0, 1/2] \\ 1 & if \quad x \in]1/2, 1] \end{cases} \tag{1.0.12}$$

That is, the direction of the velocity at time $t = n$ is :

$$\varepsilon_n(p_1(0), q_1(0)) = \chi(q_1(n)) = \chi(q_1(0) + np_1(0) + n(n-1)\alpha/2) \tag{1.0.13}$$

and the value of the variable q_2 at time $t = n+1$ is:

$$q_2(n+1) \quad = \quad q_2(n) + \chi(q_1(n)) = \sum_{1}^{n} \varepsilon_i(p_1(0), q_1(0)) \tag{1.0.14}$$

Let us denote by S_k the position of the particle along the q_2–direction at $t = k$. The equation for such a motion is expressed by the following recursion relation:

$$\begin{aligned} S_{n+1} &= S_n + \chi(q_1(n)). \\ S_0 &= 0 \end{aligned} \tag{1.0.15}$$

In terms of the variables $(x, y) \in \mathbb{T}^2$ the distance travelled by the particle along the vertical direction after n steps is:

$$S_n(x, y; \alpha) = \sum_{k=0}^{n-1} \chi(y(k)) = \sum_{k=0}^{n-1} \chi\left(y + kx + \frac{k(k-1)}{2}\alpha\right) \tag{1.0.16}$$

The problem is to study the limiting distribution of such random walk.

In the following sections, the proof will be given in steps with an increasing order of complexity, which turns out to be related to number theoretical questions. The main objective is to obtain the asymptotic behavior of the expectation values of $S_n^q(\alpha)$ for $n \longrightarrow \infty$. In the course of this study, we encounter the so-called multidimensional Gaussian sums which are a particular case of the Weyl sums [K]. They are essentially sums of the form used in the definition of theta functions, except that the summation is finite. The Gaussian sums fulfill an exact duality formula, known as Landsberg-Schaar formula [L], which is a variant of the famous Jacobi identity for theta functions. Except for the rational assumptions in the application of Schaar formula, some works had been done to estimate the growth rate of the one dimensional Gaussian sums by Hardy and Littlewood in [HL]. To this end they have first established a duality formula and then used the theory of continuous fraction decomposition (here we use tools and notations from [VdP] and [R]). We shall treat respectively in sections 3, 4 and 5 Gaussian sums in one, two and d dimensions, the central point in each part is concentrated in the proof of a duality formula for these sums.

The Gaussian sums have been more recently studied from a geometrical point of view. [DM] and [Z] have applied the results of [HL] on polynomials associated to modular functions. Interestingly one may derive this identity from a simple quantum mechanical system having the torus as phase space [AR]. But Gaussian sums are found also in other fields like the problem of fractional wave packet revival [SLB].

2 Preliminary considerations and the case of α rational

Before going into the crux of the subject, let us introduce some technical steps. The important quantity to study here is the q^{th} moment defined by:

$$E(S_n^q(\alpha)) = \int_{[0,2\pi[\times[0,2\pi[} (S_n^q(x,y;\alpha))\frac{dx.dy}{4\pi^2} \tag{2.0.1}$$

An objectve is to study the convergence of the characteristic function:

$$\Phi_n(t) = \int_{[0,2\pi[\times[0,2\pi[} e^{it.(S_n(x,y;\alpha)/\sqrt{n})}\frac{dx.dy}{4\pi^2} = \sum_{q=0}^{\infty}\frac{(it)^q}{q!}E(S_n^q(\alpha)/\sqrt{n}) \tag{2.0.2}$$

Using the Fourier decomposition of the function χ:

$$\chi(y) = \frac{2i}{\pi}\sum_{p\in\tilde{\mathbb{Z}}}\frac{e^{iPy}}{P} \tag{2.0.3}$$

where $\tilde{\mathbb{Z}}$ is the set of relative odd integers, we have an alternative form of the distance travelled by the particle:

$$S_n(x,y;\alpha) = \frac{2i}{\pi}\sum_{P\in\tilde{\mathbb{Z}}}\sum_{k=0}^{n-1}\frac{e^{iP\left(y+kx+\frac{k(k-1)}{2}\alpha\right)}}{P}. \tag{2.0.4}$$

Hence with this form one may compute the q^{th} moment. After integration on x and y, which yields two constraints:

$$\begin{aligned}\sum_{i=1}^{q} P_i &= 0\\ \sum_{i=1}^{q} k_iP_i &= 0\end{aligned} \tag{2.0.5}$$

The above expression becomes:

$$E[S_n^q(\alpha)] = \left(\frac{2i}{\pi}\right)^q\sum_{P_1\in\tilde{\mathbb{Z}}}\cdots\sum_{P_q\in\tilde{\mathbb{Z}}}\sum_{k_1=0}^{n-1}\cdots\sum_{k_q=0}^{n-1}\frac{1}{P_1\ldots P_q}e^{i2\pi\beta(P_1k_1^2+\ldots+P_qk_q^2)} \tag{2.0.6}$$

where $\beta = \frac{\alpha}{4\pi}$. We are now in a position to prove:

Lemma 2.1

$$\begin{aligned} E[S_n^{2q+1}(\alpha)] &= 0 \\ E[S_n^{2q}(\alpha)] &= (-1)^q \frac{4^q}{\pi^{2q}} \sum_{P_1 \in \tilde{\mathbb{Z}}} \cdots \sum_{P_2 q \in \tilde{\mathbb{Z}}} \sum_{k_1=0}^{n-1} \cdots \sum_{k_2 q=0}^{n-1} \frac{\delta\left(\sum_{i=2}^{2q} P_i(k_i - k_1)\right)}{P_1 \ldots P_2 q} \\ &\quad \times \exp i\pi\beta \sum_{i=2}^{2q} \sum_{j=2}^{2q} \frac{P_i P_j}{\sum_{l=2}^{2q} P_l} (k_i - k_j)^2 \end{aligned} \tag{2.0.7}$$

where $\delta(.)$ is the kronecker function: equal to 1 when the argument is 0 and 0 otherwise.

Proof. $(P_i)_{i=1,\ldots,2q}$ are odd. The condition $\sum_{i=1}^{q} P_i = 0$ can only be satisfied if q is even. Hence $E[S_n^{2q+1}(\alpha)] = 0$. Now from the constraint $\sum_{i=1}^{2q} P_i = 0$, we get $P_1 = -\sum_{i=2}^{2q} P_i$ and from $\sum_{i=1}^{2q} k_i P_i = 0$ i.e. $\sum_{i=2}^{2} q P_i(k_i - k_1) = 0$. Thus, working out k_1:

$$k_1 = \frac{\sum_{i=2}^{2q} P_i k_i}{\sum_{i=2}^{2q} P_i} \tag{2.0.8}$$

with $(k_i)_{i=2,\ldots,n-1} \in \{0, \ldots, n-1\}$. And we obtain, by substitution:

$$\begin{aligned} \sum_{i=1}^{2q} P_i k_i^2 &= \frac{1}{\sum_{i=2}^{2q} P_i} \left(\frac{1}{2} \sum_{i=2}^{2q} \sum_{j=2}^{2q} P_i P_j (k_i^2 + k_j^2) - \sum_{i=2}^{2q} \sum_{j=2}^{2q} P_i P_j k_i k_j \right) \\ &= \frac{1}{\sum_{i=2}^{2q} P_i} \left(\frac{1}{2} \sum_{i=2}^{2q} \sum_{j=2}^{2q} P_i P_j (k_i - k_j)^2 \right) \end{aligned} \tag{2.0.9}$$

which ends the proof. ■

In particular $E[S_n^2(\alpha)]$ can be exactly and directly computed :

$$E[S_n^2(\alpha)] = \frac{4}{\pi^2} \sum_{P_1 \in \tilde{\mathbb{Z}}} \sum_{P_2 \in \tilde{\mathbb{Z}}} \sum_{k_1=0}^{n-1} \sum_{k_2=0}^{n-1} \frac{e^{-i2\pi\beta(P_1 k_1^2 + P_2 k_2^2)}}{P_1 P_2} \tag{2.0.10}$$

But we get from the constraints, $P_1 = -P_2 = P$ and $k_1 = k_2 = k$. One has thus:

$$E[S_n^2(\alpha)] = \frac{4}{\pi^2} \sum_{P \in \tilde{\mathbb{Z}}} \frac{1}{P^2} \sum_{k=0}^{n-1} 1 \tag{2.0.11}$$

From the property of the Riemann Zeta-function [MOS], it may be shown that $\sum_{P\in\tilde{\mathbb{Z}}} 1/P^2 = \pi^2/4$. Hence

$$E[S_n^2(\alpha)] = n \tag{2.0.12}$$

The fact that odd moments are zero implies that the characteristic function is also even and consequently the Fourier inverse transformation of the characteristic function, that is the probability distribution function of the random variable $S_n(x, y; \alpha)$ is also even.

Finally we observe that the series

$$\sum_{(P_2,\dots,P_{2q})\in\tilde{\mathbb{Z}}^{2q-1}} \frac{1}{P_2 \dots P_{2q}(P_2 + \dots P_{2q})} \tag{2.0.13}$$

is absolutely convergent since, for all $(P_2, \dots, P_{2q}) \in \tilde{\mathbb{Z}}^{2q-1}$, $|P_2 + \dots + P_{2q}| \geq 1$. Let us prove it for $q = 2$. The generalization to arbitrary q is straighforward. The series may be split into:

$$\begin{aligned} \sum_{(P_2,P_3,P_4)\in\tilde{\mathbb{Z}}^3} \frac{1}{|P_2P_3P_4(P_2+P_3+P_4)|} &= 2 \sum_{(P_2,P_3,P_4)\in\tilde{\mathbb{N}}^3} \frac{1}{|P_2P_3P_4(P_2+P_3+P_4)|} \\ &+ 6 \sum_{(P_2,P_3,P_4)\in\tilde{\mathbb{N}}^3} \frac{1}{|P_2P_3P_4(P_2+P_3-P_4)|} \end{aligned} \tag{2.0.14}$$

Let $(x, y, z) \in [0, \infty[^3$ and $0 < \delta P < 1$ such that:

$$\begin{aligned} 1 \leq P_2 \leq x < P_2 + \delta P &\Leftrightarrow x - \delta P < P_2 \leq x \\ 1 \leq P_3 \leq y < P_3 + \delta P &\Leftrightarrow y - \delta P < P_3 \leq y \\ 1 \leq P_4 \leq z < P_4 + \delta P &\Leftrightarrow z - \delta P < P_4 \leq z \end{aligned} \tag{2.0.15}$$

The first sum in the *r.h.s.* of the equation 2.0.14 is bounded :

$$\begin{aligned} \sum_{(P_2,P_3,P_4)\in\tilde{\mathbb{N}}^3} \frac{1}{|P_2P_3P_4(P_2+P_3+P_4)|} &\leq \frac{1}{6^{1/3}} \sum_{(P_2,P_3,P_4)\in\tilde{\mathbb{N}}^3} \frac{1}{|P_2P_3P_4(P_2P_3P_4)^{1/3}|} \\ &= \frac{1}{6^{1/3}} \left(\sum_{(P)\in\tilde{\mathbb{N}}} \frac{1}{P^{1+1/3}} \right)^3 < \infty \end{aligned} \tag{2.0.16}$$

The second sum can be transformed using: $0 < (x - \delta P)(y - \delta P)(z - \delta P) \leq P_2P_3P_4 \leq xyz$ and $x + y - z - 2\delta P \leq P_2 + P_3 - P_4 \leq x + y - z + \delta P$. Hence

$$\begin{aligned} \frac{1}{|P_2P_3P_4(P_2 + P_3 - P_4)|} &\leq \frac{1}{(x - \delta P)(y - \delta P)(z - \delta P)} \\ &\quad \max\left(\frac{1}{|x + y - z - 2\delta P|}, \frac{1}{|x + y - z + \delta P|}\right) \\ &\overset{def}{=} F_{\delta P}(x, y, z) \end{aligned} \tag{2.0.17}$$

But $\forall\, \delta P < 1$, $\exists \epsilon > 0$, such that any hypercube

$$[(P_2, P_3, P_4); \ldots; (P_2 + \delta P, P_3 + \delta P, P_4 + \delta P)]$$

does not lie in the intersection $\Omega_\epsilon \overset{def}{=} [0, \infty[^3 \cap \{|x + y - z| > \epsilon\}$. Then we have

$$\begin{aligned} &\sum_{(P_2,P_3,P_4)\in\tilde{\mathbb{N}}^3} \frac{1}{|P_2P_3P_4(P_2 + P_3 - P_4)|} \\ &\leq \frac{1}{(\delta P)^3} \sum_{(P_2,P_3,P_4)\in\tilde{\mathbb{N}}^3} \int_{P_2}^{P_2+\delta P} \int_{P_3}^{P_3+\delta P} \int_{P_4}^{P_4+\delta P} F_{\delta P}(x, y, z) \\ &\leq \frac{1}{(\delta P)^3} \int_{[0,\infty[^3 \backslash \Omega_\epsilon} F_{\delta P}(x, y, z) \end{aligned} \tag{2.0.18}$$

One can easily estimate the left-hand-side by realizing that the integration of the integrals:

$$\int_{[0,\infty[^3 \backslash \Omega_\epsilon} \frac{dx.dy.dz}{|x + y - z + \delta P|} \quad \text{and} \quad \int_{[0,\infty[^3 \backslash \Omega_\epsilon} \frac{dx.dy.dz}{|x + y - z - 2\chi P|} \tag{2.0.19}$$

yields an absolutely convergent result.

2.1 $\alpha = 0$

We consider the simple case $\alpha = 0$ and show that the case with α rational can be brought back to the case $\alpha = 0$. First consider again:

$$S_n(x, y; 0) = \frac{2}{i\pi} \sum_{P\in\tilde{\mathbb{Z}}} \frac{1}{P} \sum_{k=0}^{n-1} e^{iP(kx+y)} \tag{2.1.1}$$

The above geometric sum can be reexpressed in terms of $u = e^{ix}$ and $v = e^{iy}$ as:

$$S_n(x,y;0) = \frac{2}{i\pi} \sum_{P\in\tilde{\mathbb{Z}}} \frac{1}{P} z^{-\frac{n-1}{2}P} \left(\frac{1-u^{nP}}{1-u^{P}}\right) \sum_{\epsilon=\pm 1} \epsilon u^{\epsilon P \frac{n-1}{2}} v^{\epsilon P} \tag{2.1.2}$$

Now, the $2k^{\text{th}}$ moment

$$E[S_n^{2k}(0)] = \int_{[0,2\pi[\times[0,2\pi[} \left[\frac{2}{i\pi} \sum_{P\in\tilde{\mathbb{Z}}} \frac{1}{P} \left(\sum_{k=0}^{n-1} e^{-iP(kx+y)}\right)\right]^{2k} \frac{dx.dy}{4\pi^2} \tag{2.1.3}$$

may be computed as complex integrals evaluated on the the product of the circles of unit radius and centered at 0, i.e. $\mathcal{C}(0,1)\times\mathcal{C}(0,1)$. In the domain bounded by these circles, the integrand is biholomorph and the product of the contours is homotopical to $\mathcal{C}(0,1/2)\times\mathcal{C}(0,1/2)$. Thus $(1-u^p)^{-1}$ can be expanded in power series around 0, with $u = e^{ix}$ et $v = e^{iy}$:

$$S_n(u,v;0) = \frac{2i}{\pi} \sum_{P\in\tilde{\mathbb{Z}}} u^{\frac{P}{2}} \left(\sum_{\eta=\pm 1} \eta u^{\eta n \frac{P}{2}}\right) \left(\sum_{m=0}^{\infty} u^{mP}\right) \left(\sum_{\epsilon=\pm 1} \frac{\epsilon}{P} u^{\epsilon \frac{n-1}{2} P} v^{\epsilon P}\right) \tag{2.1.4}$$

or

$$S_n(u,v;0) = \frac{2i}{\pi} \sum_{\substack{\eta=\pm 1\\ \epsilon=\pm 1}} \sum_{\substack{m\in\mathbb{N}\\ P\in\tilde{\mathbb{N}}}} \frac{\eta\epsilon}{P} u^{P\left(\frac{\epsilon+\eta}{2}n+m+\frac{1-\epsilon}{2}\right)} v^{\epsilon P} \tag{2.1.5}$$

We can now compute $E[S_n^2(0)]$ with this expression:

$$\begin{aligned} E[S_n^2(0)] \quad = \quad & -\frac{4}{\pi^2} \sum_{\substack{\eta_1,\eta_2=\pm 1\\ \epsilon_1,\epsilon_2=\pm 1}} \sum_{\substack{m_1,m_2\in N\\ P_1,P_2\in\tilde{\mathbb{N}}}} \frac{\eta_1\epsilon_1}{P_1}\frac{\eta_2\epsilon_2}{P_2} \oint \frac{dv}{2i\pi} v^{\epsilon_1 P_1+\epsilon_2 P_2} \\ & \oint \frac{du}{2i\pi} u^{P_1\left(\frac{\epsilon_1+\eta_1}{2}n+m_1+\frac{1-\epsilon_1}{2}\right)+P_2\left(\frac{\epsilon_2+\eta_2}{2}n+m_2+\frac{1-\epsilon_2}{2}\right)} \end{aligned} \tag{2.1.6}$$

The first integral over v yields $\epsilon_1 P_1 + \epsilon_2 P_2 = 0$, one must have $\epsilon_1 = -\epsilon_2$ and $P_1 = P_2 = P$. The exponent of z in the 2^{nd} integral becomes:

$$\begin{aligned} P_1\left(\frac{\epsilon_1+\eta_1}{2}n+m_1+\frac{1-\epsilon_1}{2}\right) &+ P_2\left(\frac{\epsilon_2+\eta_2}{2}n+m_2+\frac{1-\epsilon_2}{2}\right) \\ &= P\left(\frac{\eta_1+\eta_2}{2}n+m_1+m_2+1\right) \end{aligned} \tag{2.1.7}$$

The contribution to the complex integration comes only from the vanishing of this quantity. this leads to the following:

$$\eta_1=\eta_2 = -1 \tag{2.1.8}$$

$$m_1+m_2 = n-1 \tag{2.1.9}$$

and card$\{(m_1,m_2)\in\mathbb{N}^2$ tel que $m_1+m_2=n-1\}=n$, thus:

$$E[S_n^2(0)] = \sum_{\epsilon=\pm1}\sum_{p\in\tilde{\mathbb{N}}}\frac{4n}{P^2\pi^2} = \frac{4n}{\pi^2}\sum_{P\in\tilde{\mathbb{Z}}}\frac{1}{P^2} = n \tag{2.1.10}$$

This computational method may be extended to higher moments $E[S_n^{2k}(0)]$. We see that using Eq 2.1.6 to power $2k$ yields

$$E[S_n(0)^{2k}] = (-1)^k\left(\frac{4}{\pi^2}\right)^k \sum_{\eta_1,\dots\eta_{2k}=\pm1}\;\sum_{\epsilon_1,\dots\epsilon_{2k}=\pm1}\;\sum_{m_1,\dots m_{2k}\in\mathbb{N}}\;\sum_{P_1,\dots P_{2k}\in\tilde{\mathbb{N}}}$$

$$\prod_{i=1}^{2k}\frac{\eta_i\epsilon_i}{P_i}\oint\frac{dv}{2i\pi}v^{(\sum_{i=1}^{2k}\epsilon_iP_i)}\oint\frac{du}{2i\pi}u^{(\sum_{i=1}^{2k}P_i(m_i+\frac{1-\epsilon_i}{2}+\frac{\eta_i+\epsilon_i}{2}n)} \tag{2.1.11}$$

We can perform the v-integration and get:

$$\sum_{i=1}^{2k}\epsilon_iP_i = 0 \tag{2.1.12}$$

and the u-integration yields the following proposition:

Proposition 1

$$E[S_n(0)^{2k}] = (-1)^k\left(\frac{4}{\pi^2}\right)^k \sum_{\eta_1,\dots\eta_{2k}=\pm1}\;\sum_{\epsilon_1,\dots\epsilon_{2k}=\pm1}\;\sum_{m_1,\dots m_{2k}\in\mathbb{N}}\;\sum_{P_1,\dots P_{2k}\in\tilde{\mathbb{N}}}$$

$$\prod_{i=1}^{2k}\frac{\eta_i\epsilon_i}{P_i}A_n[\eta_i,\epsilon_i,P_i](2k) \tag{2.1.13}$$

where the coefficients A_n are defined as:

$$A_n[\eta_i, \epsilon_i, P_i](2k) = card\{(m_1 \dots, m_{2k}) \in I\!\!N^{2k} \mid \sum_{i=1}^{2k} m_i Pi = -\frac{1}{2}\sum_{i=1}^{2k} P_i(1 + n\eta_i)\} \tag{2.1.14}$$

with the constraint $\sum_{i=1}^{2k} \epsilon_i Pi = 0$.

This result is obtained by the *Residue Theorem.* It remains to determine the behavior of A_n as $n \to \infty$. We observe that not all the combinations of ϵ_i are to be taken into account since $(P_1, \dots, P_n) \in \tilde{\mathbb{N}}^{2k}$. Thus the choice $(\epsilon_1, \dots, \epsilon_{2k}) = (1, \dots, 1)$ is excluded by the constraint. According to the usual notation , if the $(P_i)_{i=1,\dots,r}$ do not have common divisors, we note: $(P_1, \dots, P_r) = 1$, then:

$$card\{(m_1, \dots, m_r) \in \mathbb{N}^r \mid \sum_{i=1}^{r} m_i Pi = n\} \underset{n\to\infty}{\simeq} \frac{1}{(r-1)!}\frac{n^{r-1}}{P_1 \dots P_r} \tag{2.1.15}$$

Before going on we prove the following lemma:

Lemma 2 *Let* $\sum_{i=1}^{r} \epsilon_i Pi = 0$ *and* $(P_1, \dots, P_r) = 1$ *is equivalent to* $(P_1, \dots, \hat{P}_j, \dots, P_r) = 1$ *where* P_j*, is removed.*

Proof.
It is clear that if $(P_1, \dots, \hat{P}_i, \dots, P_r) = 1$ then $(P_1, P_r) = 1$. Actually if $(P_1, \dots, \hat{P}_j, \dots, P_r) = 1$ then $\not\exists s \in \tilde{\mathbb{N}} \setminus \{1\}$ such that $\forall i \neq j,\ P_i = sp_i$ and thus $(P_1, \dots, P_q) = 1$.

Conversely if $(P_1, \dots, P_q) = 1$, but $(P_1, \dots, \hat{P}_j, \dots, P_r) = s$ with $s \in \tilde{\mathbb{N}} \setminus \{1\}$, i.e. $\forall i \neq j,\ P_i = sp_i$, then $P_j = \sum_{i\neq j} \epsilon_i \epsilon_j P_i = s(\sum_{i \neq j} \epsilon_i \epsilon_j p_i)$ which contradicts the fact that $(P_1, \dots, P_q) = 1$. ■

Coming back to our estimate of A_n, put $\bar{\mathbb{N}}^q = \tilde{\mathbb{N}}^q \cap \{(P_1, \dots, P_q) = 1\}$. If $(P_1, \dots, P_{2k}) \in \bar{\mathbb{N}}^{2k}$ such that $\sum_{i=1}^{2k} \epsilon_i P_i = 0$ then:

$$\begin{aligned} A_n[\eta_i, \epsilon_i, P_i](2k) \quad & \underset{n\to\infty}{\sim} \quad \frac{(-1)^{2k-1}}{(2k-1)!}\frac{1}{\prod_{i=1}^{2k} P_i}\left(\frac{n.\sum_{i=1}^{2k} P_i \eta_i}{2}\right)^{2k-1} \quad \text{if } \sum_{i=1}^{2k} \eta_i P_i < 0 \\ & = \quad \begin{cases} 1 & if\ \sum_{i=1}^{2k} \eta_i P_i = 0 \\ 0 & otherwise \end{cases} \end{aligned} \tag{2.1.16}$$

with $\sum_{i=1}^{2k} \epsilon_i P_i = 0$. Now from Eq 2.1.16 the asymptotic behavior for $n \to \infty$ of the $2k^{\text{th}}$ moment is:

$$E[S_n^{2k}(0)] \underset{n\to\infty}{\sim} 2\frac{(-1)^k}{(2k-1)!\pi^{2k}} \sum_{P\in\tilde{\mathbb{N}}} \frac{1}{P^{2k}} \sum_{\substack{\eta_i=\pm 1\\ \epsilon_i=\pm 1}} \sum_{P_i\in\tilde{N}^{2k}} \prod_{i=1}^{2k} \frac{\epsilon_i\eta_i}{P_i^2} \left(\sum_{i=1^{2k}} \eta_i P_i\right)^{2k-1} n^{2k-1} \tag{2.1.17}$$

with $\sum_{i=1}^{2k} \epsilon_i P_i = 0$ and $\sum_{i=1}^{2k} \eta_i P_i > 0$. We have already seen that the series

$$\sum_{\substack{\eta_1,\ldots,\eta_{2k}=\pm 1\\ \epsilon_1,\ldots,\epsilon_{2k}=\pm 1}} \sum_{\substack{P_1,\ldots,P_{2k}\in\tilde{N}^{2k}\\ \sum_{i=1}^{2k}\epsilon_i P_i=0}} \prod_{i=1}^{2k} \frac{\epsilon_i\eta_i}{P_i^2} \left(\sum_{i=0}^{2k} \eta_i P_i\right)^{2k-1} \tag{2.1.18}$$

is an absolutely convergent series. Since $\sum_{P\in\tilde{\mathbb{N}}} \frac{1}{P^q} \xrightarrow[q\to\infty]{} 1$, we have thus the theorem:

Theorem 2.2 *$\forall k \in I\!N$, $E[S_n^{2k}(0)] \underset{n\to\infty}{\sim} C_k n^{2k-1}$ with*

$$C_1 = 1$$
$$C_k = 2\frac{(-1)^k}{(2k-1)!\pi^{2k}} \sum_{\substack{\eta_i,\epsilon_i=\pm 1\\ P_i\in\tilde{N}^{2k}}} \prod_{i=1}^{2k} \frac{\epsilon_i\eta_i}{P_i^2} \left(\sum_{i=1}^{2k} \eta_i P_i\right)^{2k-1} \tag{2.1.19}$$

with $\sum_{i=0}^{2k} \epsilon_i P_i = 0$ and $\sum_{i=0}^{2k} \eta_i Pi > 0$.

2.2 Extension to rational β ($\alpha \in \mathbb{Q}$)

To this end, we regroup terms of $S_n(x, y; \alpha)$. $\forall \alpha \in \mathbb{Q}$, $\exists k_0 \in I\!N$ such that $\forall k < k_0$:

$$\begin{aligned} k(k-1)\beta &\not\equiv 0 \mod (1) \\ k_0(k_0-1)\beta &\equiv 0 \mod (1) \end{aligned} \tag{2.2.1}$$

We shall set $n = qk_0$ and write $S_n(x, y; \alpha)$ grouping the terms such that:

$$\delta_s(x, y) = \sum_{n=0}^{q-1} \chi\left(y + [s + nk_0]x + 2s(s-1)\pi\beta\right) \tag{2.2.2}$$

and

$$S_n(x,y;\alpha) = \sum_{s=0}^{k_0-1} \delta_s(x,y) \tag{2.2.3}$$

with $0 < s \leq k_0$. The sum can be partially performed after inserting the definition of χ:

$$\begin{aligned}\delta_s(x,y) = \frac{2}{i\pi}\sum_{P\in\tilde{\mathbb{Z}}} \frac{1}{P} e^{-ik_0\frac{P(P-1)}{2}x} \left(\frac{e^{iPqk_0x}-1}{e^{iPk_0x}-1}\right) \\ \left(e^{iP(y+x[s+\frac{k_0(q-1)}{2}]+2s(s-1)\beta)} - e^{-iP(y+x[s+\frac{k_0(q-1)}{2}]+2s(s-1)\beta)}\right)\end{aligned} \tag{2.2.4}$$

Call now $s' = 2s(s-1)$, $u = e^{ix}$, $v = e^{iy}$ and $t = e^{2i\beta}$. Then

$$\begin{aligned}\delta_s(x,y;\alpha) &= \delta_s(u,v;t) = \frac{2}{i\pi}\sum_{P\in Zz} \frac{1}{P} u^{-k_0\frac{P(P-1)}{2}} \left(\frac{1-z^{Pqk_0}}{1-z^{Pk_0}}\right) \\ &\sum_{\epsilon=\pm1} \epsilon z^{\epsilon P(s+\frac{q-1}{2}k_0)} v^{\epsilon P} t^{\epsilon P s'}\end{aligned} \tag{2.2.5}$$

We now expand $\frac{1}{1-u^{Pk_0}}$ as in the previous section, and obtain consequently:

$$\delta_s(u,v;t) = \frac{2}{i\pi}\sum_{\epsilon,\eta=\pm1}\sum_{P\in\tilde{\mathbb{Z}},m\in\mathbb{N}} \frac{\epsilon\eta}{P} v^{\epsilon P} t^{\epsilon P s'} u^{P(\epsilon s+k_0\frac{1-\epsilon}{2}+mk_0+qk_0\frac{\eta+\epsilon}{2})} \tag{2.2.6}$$

The expectation value:

$$\begin{aligned}E(\delta_{s_1}(t)\ldots\delta_{s_{2k}}(t)) = (-1)^q\left(\frac{4}{\pi}\right)^q \sum_{\substack{\eta_i,\epsilon_i=\pm1 \\ P_i\in\tilde{\mathbb{N}},m_i\in\mathbb{N}}} \prod_{i=1}^{2k} \frac{\eta_i\epsilon_i}{P_i} t^{(\sum_{i=1}^{2k}\epsilon_i P_i s'_i)} \\ \oint \frac{dv}{2i\pi v} v^{(\sum_{i=1}^{2k}\epsilon_i P_i)} \oint \frac{du}{2i\pi u} u^{(\sum_{i=1}^{2k} P_i(\epsilon_i s_i+k_0\frac{1-\epsilon_i}{2}+m_i k_0+qk_0\frac{\eta_i+\epsilon_i}{2}))}\end{aligned} \tag{2.2.7}$$

is not zero if $\sum_{i=1}^{2k} P_i(\epsilon_i s_i + k_0\frac{1-\epsilon_i}{2} + m_i k_0 + qk_0\frac{\eta_i+\epsilon_i}{2}) = 0$ and $\sum_{i=1}^{2k}\epsilon_i P_i = 0$. As before, one can reduce to the case $(P_1,\ldots,P_{2k}) = 1$. The first assertion is true if $\sum_{i=0}^{2k_0}\epsilon_i P_i s_i$ is divisible by k_0, with $0 \leq s_i < k_0$. The hypothesis on P_i suggests that there exists a P_{i_0} not divisible by k_0.

Lemma 3 *Let* $s_1, \ldots, s_{2k}$ *such that* $\sum_{i=0}^{2k_0} \epsilon_i P_i s_i$ *is divisible by* k_0 *then* $\forall s \in \{1, \ldots, k_0\}$ *and* $s \neq s_{i_0}$*,* k_0 *is not a divisor of* $\sum_{i=0}^{2k_0} \epsilon_i P_i s_i$*.*

Proof. Suppose that this assertion is not true: $\exists n$ such that $\sum_{i=0}^{2k_0} \epsilon_i P_i s_i = nk_0$ and $\exists n'$ such that $\sum_{i=0}^{2k_0} \epsilon_i P_i s_i = n'k_0$. Hence $\epsilon_{i_0} P_{i_0}(s_{i_0} - s) = (n - n')k_0$ but k_0 is not a divisor of P_{i_0} and $|s_{i_0} - s| < k_0$, this is not possible. ■

Consequently card$\{(s_1, \ldots, s_2k) \in \{1, \ldots, k_0\}^{2k}\}$ such that k_0 is not a divisor of $\sum_{i=1}^{2k} \epsilon_i P_i s_i$ and the value $(P_i)_{i=1,\ldots,2k}$ are mutually prime numbers of values less than k_0^{2k-1}.

Remark 4

We have

$$\text{card}\left[(m_1, \ldots, m_{2k}) \in \mathbb{N}^{2k} | \sum_{i=1}^{2k} P_i(\epsilon_i s_i + k_0 \frac{1 - \epsilon_i}{2} + m_i k_0 + q k_0 \frac{\eta_i + \epsilon_i}{2}) = 0\right]$$

$$\underset{q \to \infty}{\simeq} \text{card}[(m_1, \ldots, m_{2k}) \in \mathbb{N}^{2k} | \sum_{i=1}^{2k} m_i P_i = -\frac{q}{2} \sum_{i=1}^{2k} \eta_i P_i] \tag{2.2.8}$$

with $(P_1, \ldots, P_{2k}) = 1$. Since $\sum_{i=1}^{2k} \epsilon_i P_i = 0$ and $t^{P \sum_{i=1}^{2k} \epsilon_i P_i s'_i} = t^{P \sum_{i=1}^{2k} \epsilon_i P_i s_i^2/2}$. Following the previous procedure we obtain for $n = qk_0$.

$$E[S_{qk_0}^{2k}(\alpha)] \underset{q \to \infty}{\simeq} \frac{2(-1)^k}{\pi^{2k}(2k-1)!}(qk_0)^{2k-1} \sum_{\substack{\eta_i, \epsilon_i = \pm 1 \\ P_i \in \tilde{\mathbb{N}}}} \prod_{i=1}^{2k} \frac{\eta_i \epsilon_i}{P_i^2} \left(\sum_{i=1}^{2k} \eta_i P_i\right)^{2k-1} \frac{1}{k_0^{2k-1}}$$

$$\sum_{p \in \tilde{\mathbb{N}}} \sum_{s_i=1}^{k_0} \frac{t^{P \sum_{i=1}^{2k} \epsilon_i P_i s_i^2/2}}{P^{2k}} \tag{2.2.9}$$

with the conditions $\sum_{i=1}^{2k} \epsilon_i P_i = 0$,$\sum_{i=1}^{2k} \epsilon_i P_i s_i$ is divisible by k_0 , $(P_1, \ldots, P_{2q}) = 1$ and $\sum_{i=1}^{2k} \eta_i P_i \geq 0$. As it was mentionned , for all $P \in \tilde{\mathbb{N}}$, we have

$$\left| \frac{1}{k_0^{2k-1}} \sum_{s_i=1}^{k_0} t^{P/2 \sum_{i=1}^{2k} \epsilon_i P_i s_i^2} \right| < 1 \tag{2.2.10}$$

Note that for $\alpha = 0$ ($k_0 = 1$) this term is simply 1. Consequently we have the theorem:

Theorem 2.3 *$\forall \alpha \in \mathbb{Q}$, $\forall k \in I\!N^*$ $E[S_n^{2k}(\frac{\pi\beta}{4})] \underset{n\to\infty}{\simeq} C_k n^{2k-1}$ with $C_1 = 1$ and C_k a constante.*

This result suggests a unique normalization, for which the characteristic function of $S_n(x,y;\alpha)$ once normalized will be independent of n, when $n \to \infty$:

$$\phi_{\frac{S_n}{n}}(t) \underset{n\to\infty}{\simeq} \sum_{k=0}^{\infty} \frac{(it)^{2k}}{(2k)!} C_k \frac{n^{2k-1}}{n^{2k}} = 1 \tag{2.2.11}$$

Consequently the probability distribution function F of the normalized random variable limit $S = \lim_{n\to\infty} \frac{S_n(x,y;\alpha)}{n}$, for $\alpha \in \mathbb{Q}$:

$$F(S) = \delta \tag{2.2.12}$$

where δ is the Dirac distribution. That follows in fact from the ergodic Birkhoff theorem, but the speed of the convergence to zero of $\frac{S_n(x,y;\alpha)}{n}$ is very slow.

3 The case of irrational β in terms of Gaussian sums

In this section we shall proceed with a different type of estimate of $E(S_n^{2q}(\alpha))$ for $\alpha \in \mathbb{R}^*$. In particular, we emphasize the difference between the rational case of section 2 and the irrational case $\alpha \in \mathbb{R} \setminus \mathbb{Q}$. For this purpose, we shall establish a generalization of the duality formula for one-dimensional Gaussian sums, given in the celebrated work of Hardy and Littlewood [HL]. This problem consists in estimating the behavior of the many variable sums, for large n:

$$\sum_{k_1=0}^{n-1} \cdots \sum_{k_{2q}=0}^{n-1} e^{i\frac{\alpha}{4}\sum_{i=2}^{2q}\sum_{j=2}^{2q}\frac{P_iP_j}{\sum_{i=2}^{2q}P_i}(k_i-k_j)^2} \tag{3.0.1}$$

where $P_i \in \tilde{\mathbb{Z}}$, $i = 2, \ldots, 2q$ are parameters (see Eq.2.0.7). The above sum bears over integer in indices of $\mathbb{N}^{2q}$ formed by intersection of the hypercube of total volume n^{2q} and the hyperplane defined by the equation:

$$\sum_{i=2}^{2q} P_i(k_i - k_1) = 0 \tag{3.0.2}$$

This condition can be recast as an integral using the formulae:

$$\begin{aligned} \int_0^1 e^{2\pi i x P} dx &= 1 \; if \; P = 0 \\ &= 0 \; if \; P \in \mathbb{N}^* \end{aligned} \tag{3.0.3}$$

Define now, the quantity:

$$\begin{aligned} &\xi_n[x, \beta; P_2, \ldots, P_{2q}] = \\ &\sum_{k_1=0}^{n-1} \cdots \sum_{k_{2q}=0}^{n-1} e^{i\pi\beta \sum_{i=2}^{2q} \sum_{j=2}^{2q} \frac{P_i P_j}{\sum_{i=2}^{2q} P_i} (k_i - k_j)^2} e^{2i\pi x \sum_{i=2}^{2q} P_i (k_i - k_1)} \end{aligned} \tag{3.0.4}$$

Then, the $2q^{\text{th}}$ (see Eq.2.0.7) moment may be rewritten as:

$$\begin{aligned} &E[S_n^{2q}(\frac{\pi\beta}{4})] = (-1)^q \left(\frac{4}{\pi}\right)^q \\ &\sum_{P_i \in \tilde{\mathbb{Z}}} \frac{1}{\prod_{i=2}^{2q} P_i (\sum_{i=2}^{2q} P_i)} \int_0^1 \xi_n[x, \beta; P_2, \ldots, P_{2q}] dx \end{aligned} \tag{3.0.5}$$

As $\xi_n[x, \beta; P_2, \ldots, P_{2q}]$ are analogous to $2q$ variables theta functions [M], we shall express the formula Eq. 3.0.5 in terms of Gaussian sums ${}^d\sigma_{A_{\vec{n}}}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta})$.

Definition 5 *we define the d-dimensional Gaussian sums:*

$${}^d\sigma_{A_{\vec{n}}}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) = \sum_{\vec{k} \in A_{\vec{n}}} e^{i\pi\, {}^t(\vec{k} - \frac{\vec{a}}{2}) \Omega (\vec{k} - \frac{\vec{a}}{2})} e^{2i\pi\, {}^t(\vec{k} - \frac{\vec{a}}{2})(\vec{\theta} - \frac{\vec{b}}{2})} \tag{3.0.6}$$

Where Ω *is a* d *square matrix with real coefficients:* $\Omega \in M_d(I\!R)$, $\vec{\theta} \in Vect_d(I\!R)$ *such that* $\forall i = 1, \ldots, d$, *the component* θ_i *of* $\vec{\theta}$ *is restricted to* $0 < \theta_i < 1$. *Here we denote by* ${}^t\vec{v}$ *the transpose of a vector* $\vec{v}$. *Moreover* $\vec{a}$ *and* $\vec{b}$ *are elements of* $Vect_d(\{0, 1\})$. $A_{\vec{n}}$, *with* $\vec{n} = (n_1, \ldots, n_d)$, *is the hyper-rectangle with integer sites in* $I\!N^d$ *defined by:*

Any $\vec{k} \in A_{\vec{n}}$ *is such that* $\forall i = 1, \ldots, d$, $0 \leq k_i \leq n_i - 1$, $k_i \in I\!N$.
With this notation:

$$\xi_n[x, \beta; P_2, \ldots, P_{2q}] = \sum_{k_1=0}^{n-1} e^{-2i\pi x (\sum_{i=2}^{2q} P_i) k_1} . {}^{2q-1}\sigma_{A_{\vec{n}}}^{[\vec{0},\vec{0}]}(\Omega, \vec{\theta}) \tag{3.0.7}$$

where:

- *$A_{\vec n}$ defined by the $2q-1$-vector $\vec n$: $\vec n = (n-1, \dots, n-1)$*
- *the $2q-1$-square matrix Ω:*

$$\Omega = \frac{\beta}{\sum P_i}\begin{bmatrix} P_2(\sum_{i=2}^{2q} P_i - P_2) & -P_2P_3 & \dots & -P_2P_{2q} \\ -P_2P_3 & P_3(\sum_{i=2}^{2q} P_i - P_3) & \vdots & -P_3P_{2q} \\ \vdots & \vdots & \ddots & \vdots \\ -P_2P_{2q} & -P_3P_{2q} & \dots & P_{2q}(\sum_{i=2}^{2q} P_i - P_{2q}) \end{bmatrix} \tag{3.0.8}$$

- *the $2q-1$-vector θ:*

$$\vec\theta = x\begin{bmatrix} P_2 \\ P_3 \\ \vdots \\ P_{2q} \end{bmatrix} \in Vect_{2q-1}(I\!R) \tag{3.0.9}$$

- $\vec a = \vec b = \vec 0$

In order to compute the above sum, we shall first establish the duality formula:

Theorem 3.1 (duality formula) *If $\Omega \in M_d(]0,1[)_{sym,inv}$ (the d-dimensional symmetric and invertible matrices with values in]0,1[), $\vec\theta \in Vect_d(]0,1[)$, and $(\vec a, \vec b) \in Vect_d(\{0,1\})$, then*

$$ {}^d\sigma_{\mathcal{D}}^{[\vec a,\vec b]}(\Omega,\vec\theta) = \tag{3.0.10}$$

$$\left(\frac{i}{\sqrt{\det\Omega}}\right)^{\frac{d}{2}} e^{-i\pi\,{}^t\vec\theta\Omega^{-1}\vec\theta}\left(\sum_{0\le i_1,\dots,i_d\le d}\mathcal{O}(1)^{i_1+\dots+i_d}.{}^d\sigma^{[\vec b,\vec a]}_{\mathcal{P}_{i_1}\dots\mathcal{P}_{i_d}(\Omega\mathcal{D})}(-\Omega^{-1},\Omega^{-1}\vec\theta)\right)$$

where $\mathcal{D}$ is a domain of $\mathbb{N}^d$ and $\Omega(\mathcal{D})$ is the set of integers sites of $\mathbb{N}^d$ contained in the image of $\mathcal{D}$ by Ω and $\mathcal{P}_i$ is the projection on $\{k_i = 0\}$. Moreover we take the convention $\mathcal{O}(1)^0 = 1$.

This duality formula will be extended to $\Omega \in M_d(\mathbb{R})_{sym,inv}$ (d-dimensional real symmetric and invertible matrices) and later we shall treat the case of singular Ω, i.e.: $\det(\Omega) = 0$.

3.1 Results of Hardy and Littlewood on one-dimensional Gaussian sums

Following [HL], let us introduce:

$$\begin{aligned} C_n^2(x,\theta) &= \sum_{k=0}^{n-1} e^{i\pi x(k-1/2)^2}\cos(2k-1)\pi\theta \\ C_n^3(x,\theta) &= \sum_{k=0}^{n-1} e^{i\pi xk^2}\cos 2k\pi\theta \\ C_n^4(x,\theta) &= \sum_{k=0}^{n-1}(-1)^k e^{i\pi xk^2}\cos 2k\pi\theta \qquad (3.1.1) \end{aligned}$$

Then, the duality formula for the Gaussian sum $C_n^3(x,\theta)$ (see Eq. 3.1.7 below) can be obtained by application of the residue theorem in the formula [HL]:

$$C_n^3(x,\theta) = \sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}C_{nx}^3(-\frac{1}{x},\frac{\theta}{x}) + i\int_0^\infty \frac{e^{-\pi x(n^2-t^2)}}{\sinh \pi t}Q_n(\theta,x,t)dt \quad (3.1.2)$$

with $0 < x < 1$ and $0 < \theta < 1$. The function $Q_n(\theta,x,t)$ is given by:

$$\begin{aligned} Q_n(\theta,x,n) &= \cos(2\pi n\theta)\cosh(2\pi\theta t)\sinh((2nx-2k-1)\pi t) \quad (3.1.3) \\ &+ i\sin(2\pi n\theta)\sinh(2\pi\theta t)\cosh((2nx-2k-1)\pi t) \end{aligned}$$

Observe that the integral in this equation may be reduced to integrals of the type :

$$\int_0^\infty e^{i\pi x(n^2-t^2)}e^{2\pi\theta t}\frac{\sinh(\alpha\pi t)}{\sinh(\pi t)}dt. \quad (3.1.4)$$

From the theorem on intermediate values we have: $\exists T$ bounded, such that $\forall\theta \in]0,1[$, the previous integral is

$$\mathcal{O}(1)e^{-\pi n^2 x}\int_0^{T(\theta)} e^{i\pi xt^2}e^{2\pi\theta t}dt \quad (3.1.5)$$

where $\mathcal{O}(1)$ means a bounded function with respect to θ. This integral depends on θ but remains bounded. The validity of this theorem is guaranteed since $\frac{\sinh(\alpha\pi t)}{\sinh(\pi t)}$ is a positive decreasing function of θ on $\mathbb{R}^+$. Its value is:

$$\mathcal{O}(1)\sqrt{\frac{i}{x}}e^{-\pi\frac{\theta^2}{x}}\left(\operatorname{erf}(T\sqrt{i\alpha}-\frac{b}{\sqrt{i\alpha}}) - \operatorname{erf}(\frac{b}{\sqrt{i\alpha}})\right) \quad (3.1.6)$$

where the function erf (the error function) is defined as $\mathrm{erf}(z) \mapsto \int_0^z e^{-i\pi v^2} dv$ This leads to a more precise form of the result of Hardy et Littelwood. A similar proof can be performed for C_n^2 and C_n^4. In fact we have obtained the proposition:

Proposition 6 *We have the following duality formulas:* $\forall 0 < x < 1$ *and* $\forall 0 < \theta < 1$

$$\begin{aligned} C_n^2(x,\theta) &= \sqrt{\frac{i}{x}} e^{-i\pi \frac{\theta^2}{x}} \left(C_{nx}^4\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1) \right) \\ C_n^3(x,\theta) &= \sqrt{\frac{i}{x}} e^{-i\pi \frac{\theta^2}{x}} \left(C_{nx}^3\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1) \right) \\ C_n^4(x,\theta) &= \sqrt{\frac{i}{x}} e^{-i\pi \frac{\theta^2}{x}} \left(C_{nx}^2\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1) \right) \end{aligned} \tag{3.1.7}$$

In their work, Hardy and Littlewood, have stated that analogous sums with sine instead cosine obey also duality formulas which can be established in a similar way. However as already seen, the parity of the cosine function does play an important role. When the cosine is replaced by the sine, there appears Fresnel functions which need additional treatment. We offer here an alternative proof. Define:

$$C_{q,q+r}^3(x,\theta) = \sum_{k=q+1}^{q+r} e^{i\pi x k^2} \cos(2k\pi\theta) = C_{q+r}^3(x,\theta) - C_q^3(x,\theta) \tag{3.1.8}$$

Applying the duality formula on $C_q^3(x,\theta)$ we find:

$$C_{q,q+r}^3(x,\theta) = \sqrt{\frac{i}{x}} e^{-i\pi \frac{\theta^2}{x}} \left(C_{nq,n(q+r)}^3\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1) \right). \tag{3.1.9}$$

But we also have:

$$C_{q,q+r}^3(x,\theta) = \sum_{k=q+1}^{q+r} e^{i\pi x k^2} \cos(2\pi k\theta) = \sum_{k=1}^{q+r} e^{i\pi x (k+q)^2} \cos 2\pi(k+q)\theta \tag{3.1.10}$$

after expansion of the cosine, we obtain:

$$
\begin{aligned}
C^3_{q,q+r}(x,\theta) = \frac{e^{-\pi x q^2}}{2}\sum_{k=1}^{r} e^{i\pi x k^2}(\cos 2\pi\theta q \qquad\qquad (3.1.11)\\
&[\cos 2\pi(xq+\theta)k + \cos 2\pi(xq-\theta)k + i(\sin 2\pi(xq+\theta)k + \sin 2\pi(xq+\theta)k)]\\
+ \; &\sin 2\pi\theta q\\
&[\sin 2\pi(xq+\theta)k - \sin 2\pi(xq-\theta)k - i(\sin 2\pi(xq+\theta)k + \sin 2\pi(xq+\theta)k)])
\end{aligned}
$$

Assume now $x \in \mathbb{Q}$, such that $x = a/b$, where a and b are prime numbers. We choose now e_1 as multiple of b and let $e(xq)$ label the integer part of xq:

$$
\begin{aligned}
C^3_{q,q+r}(x,\theta) &= (-1)^{qe(xq)} \qquad (3.1.12)\\
&\left[\cos 2\pi q\theta \sum_{k=0}^{r-1} e^{i\pi x k^2}\cos 2\pi\theta k - \sin 2\pi q\theta \sum_{k=0}^{r-1} e^{i\pi x k^2}\sin 2\pi\theta k\right].
\end{aligned}
$$

Using the duality formula we obtain:

$$
\begin{aligned}
C^3_{q,q+r}(x,\theta) &= (-1)^{qe(xq)}\cos 2\pi q\theta\sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\left(C^3_{xr}\left(-\frac{1}{x},\frac{\theta}{x}\right)+\mathcal{O}(1)\right)\\
&-(-1)^{qe(xq)}\sin 2\pi q\theta\sum_{k=0}^{r-1} e^{i\pi s k^2}\sin 2\pi\theta k. \qquad (3.1.13)
\end{aligned}
$$

Moreover we have

$$
\begin{aligned}
&\sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\left(C^3_{xr}\left(-\frac{1}{x},\frac{\theta}{x}\right)+\mathcal{O}(1)\right) = \sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\sum_{k=0}^{e(xr)-1}\sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\\
&(-1)^{qe(xq)}e^{-i\pi\frac{(k+e(xq))^2}{x}}\cos 2\pi\frac{k+e(xq)}{x}\theta\left[\cos 2\pi\frac{e(xq)}{x}\theta\sum_{k=0}^{e(xr)-1} e^{-i\pi\frac{k^2}{x}}\right.\\
&\left.\cos 2\pi\frac{k}{x}\theta - \sin 2\pi\frac{e(xq)}{x}\theta\sum_{k=0}^{e(xr)-1} e^{-i\pi\frac{k^2}{x}}\sin 2\pi\frac{k}{x}\theta + \mathcal{O}(1)\right] \qquad (3.1.14)
\end{aligned}
$$

This leads to the equality:

$$\begin{aligned}&\cos 2\pi\theta q\left(C^3_{xr}\left(\frac{-1}{x},\frac{\theta}{x}\right)+\mathcal{O}(1)\right)-\sqrt{\frac{x}{i}}\sin 2\pi q\theta\sum_{k=0}^{e(xr)-1}e^{i\pi\frac{\theta^2-k^2}{x}}\sin 2\pi\frac{k}{x}\theta\\&=C^3_{xr}\left(\frac{-1}{x},\frac{\theta}{x}\right)\cos 2\pi\frac{e(xq)}{x}\theta-S^3_{xr}\left(\frac{-1}{x},\frac{\theta}{x}\right)\sin 2\pi\frac{e(xq)}{x}\theta+\mathcal{O}(1)\end{aligned}\tag{3.1.15}$$

when q is given as a multiple of b, we get simply:

$$S^3_r(x,\theta)=\sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\left[S^3_{xr}\left(\frac{-1}{x},\frac{\theta}{x}\right)+\mathcal{O}(1)\right]\tag{3.1.16}$$

$\forall\theta$ such that $2\pi q\theta\neq\pi k$ or $\theta\not\equiv\frac{k}{2q}\mod(1)$. Let us now call

$$\zeta_q=\left\{\theta\in]0,1[\quad\exists k\in\mathbb{N}\quad\text{such that}\quad\theta\equiv\frac{k}{2q}\mod(1)\right\}\tag{3.1.17}$$

But $\forall\theta$, $\exists q'$ a multiple of b such that $\theta\notin\zeta_{q'}$.

Hence, $\forall\theta\in]0,1[$ and $\forall x\in\mathbb{Q}$, we obtain the same duality formula . Finally $S_r(x,\theta)$ is a continuous function and bicontinuous since it is a finite sum of bicontinuous functions. As $\mathbb{Q}$ is dense $\mathbb{R}$. $\forall x\in]0,1[$, $\exists x_n\in\mathbb{Q}\backslash]0,1[$, $n\in\mathbb{N}$ such that $\lim_{n\to\infty}x_n=x$ and by continuity we obtain the limits:

$$\begin{aligned}\lim_{n\to\infty}S^3_r(x_n,\theta)&=S^3_r(x,\theta)\\\lim_{n\to\infty}S^3_{xr}\left(\frac{-1}{x_n},\frac{\theta}{x_n}\right)&=S^3_{xr}\left(\frac{-1}{x},\frac{\theta}{x}\right)\end{aligned}\tag{3.1.18}$$

Doing the same proof for $S^2_n(x,\theta)$ and $S^4_n(x,\theta)$ we get the following duality formulas:

$$\begin{aligned}S^2_n(x,\theta)&=\sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\left(S^4_{nx}\left(-\frac{1}{x},\frac{\theta}{x}\right)+\mathcal{O}(1)\right)\\S^3_n(x,\theta)&=\sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\left(S^3_{nx}\left(-\frac{1}{x},\frac{\theta}{x}\right)+\mathcal{O}(1)\right)\\S^4_n(x,\theta)&=\sqrt{\frac{i}{x}}e^{-i\pi\frac{\theta^2}{x}}\left(S^2_{nx}\left(-\frac{1}{x},\frac{\theta}{x}\right)+\mathcal{O}(1)\right)\end{aligned}\tag{3.1.19}$$

These results are used to show that, for the following Gaussian sums:

$$ {}^1\sigma_n^{[a,b]}(x,\theta) = \sum_{k=0}^{n-1} e^{-i\pi x(k-a/2)^2} e^{2i\pi(k-a/2)(\theta-b/2)} \tag{3.1.20}$$

with $a = 1, 0$ and $b = 0, 1$, we have $\forall x \in]0, 1[$ and $\theta \in]0, 1[$:

$$ {}^1\sigma_n^{[a,b]}(x,\theta) = \sqrt{\frac{i}{x}} e^{-i\pi\frac{\theta^2}{x}} \left({}^1\sigma_{nx}^{[a,b]}\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1)\right) \tag{3.1.21}$$

we summurise these results in the following:

Theorem 3.2 *$\forall x \in]0, 1[, \forall\theta \in]0, 1[, \forall a, b = 0, 1$:*

$$\begin{aligned} {}^1\sigma_n^{[a,b]}(x,\theta) &= \sqrt{\frac{i}{x}} e^{-i\pi\frac{\theta^2}{x}} \left({}^1\sigma_{nx}^{[b,a]}\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1)\right) \\ C_n^{[a,b]}(x,\theta) &= \sqrt{\frac{i}{x}} e^{-i\pi\frac{\theta^2}{x}} \left(C_{nx}^{[b,a]}\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1)\right) \\ S_n^{[a,b]}(x,\theta) &= \sqrt{\frac{i}{x}} e^{-i\pi\frac{\theta^2}{x}} \left(S_{nx}^{[b,a]}\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1)\right) \end{aligned} \tag{3.1.22}$$

Upon application of duality $\forall x \in]0, 1[, \forall\theta \in]0, 1[, \forall a, b = 0, 1$, we have:

$$\begin{aligned} {}^1\sigma_n^{[a,b]}(-x,\theta) &= \left[{}^1\sigma_n^{[a,b]}(x,\theta)\right]^* \\ &= \left[\sqrt{\frac{i}{x}} e^{-i\pi\frac{\theta^2}{x}} \left({}^1\sigma_{nx}^{[a,b]}\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1)\right)\right]^* \\ &= \frac{e^{-i\frac{\pi}{4}}}{\sqrt{x}} e^{i\pi\frac{\theta^2}{x}} \left[{}^1\sigma_{nx}^{[b,a]}\left(-\frac{1}{x}, \frac{\theta}{x}\right) + \mathcal{O}(1)\right]^* \\ &= \frac{e^{-i\frac{\pi}{4}}}{\sqrt{-x}} e^{i\pi\frac{\theta^2}{-x}} \left[{}^1\sigma_{-nx}^{[b,a]}\left(-\frac{1}{-x}, \frac{\theta}{-x}\right) + \mathcal{O}(1)\right]^* \end{aligned} \tag{3.1.23}$$

we extend the validity of the duality formula to $x \in \mathbb{R} \setminus \mathbb{N}$. Using the convention $\sqrt{-1} = i$, the identity formula can be extended for $-1 < x < 1$ and $x \neq 0$. All this remain valid for C_n and S_n, since we have the identity:

$$ {}^1\sigma_n^{[a,b]}(x,\theta) = C_n^{[a,b]}(x,\theta) + i.S_n^{[a,b]}(x,\theta) \tag{3.1.24}$$

Finally we also have the formula:

$$^{1}\sigma_{n}^{[a,b]}(x+1,\theta)=\sqrt{i}^{a}\,{}^{1}\sigma_{n}^{[a,b']}(x,\theta) \tag{3.1.25}$$

with $b'\equiv b+a \mod (1)$, it may be used to extend the validity domain of the formula into $x\in\mathbb{R}\setminus\mathbb{Z}$. If $x\in\mathbb{Z}$, the series reduces to a geometric series. The same results hold for C_n and S_n.

Remark 7

If $x\in\mathbb{Q}$, there exists a discrete duality formula (Shaar's formula). This relation is actually the same as our formulas without the term $\mathcal{O}(1)$. The formulas are used in successive iterations until the summations are limited to a small number. The domain of summation is reduced at each step. However the result depends on its expansion as a continuous fraction (see article Hardy and Littlewood). This last problem is closely related to the Gauss transform $T(x)\equiv\frac{1}{x} \mod (1)$ for which there exists infinite generating partitions. So for example if x is irrational, but admits a decomposition into continuous bounded fractions we have:

$$^{1}\sigma_{n}^{[a,b]}(x,\theta)\simeq\mathcal{O}(\sqrt{n}) \tag{3.1.26}$$

a homogenous function in θ. But if $x\in\mathbb{Q}$:

$$^{1}\sigma_{n}^{[a,b]}(x,\theta)\simeq\mathcal{O}(n). \tag{3.1.27}$$

4 Two-dimensional gaussians sums

4.1 Two-dimensional Gaussian sums with non-degenerate matrix Ω

Once this case treated, one can extend the results to Gaussian sums of arbitrary dimensions, provided some delicate points are worked. Consider the Gaussian sum in two dimensions:

$$^{2}\sigma_{A_{\vec{q}}}^{[0,0]}(\Omega,\vec{\theta})=\sum_{k_1=0}^{q_1-1}\sum_{k_2=0}^{q_2-1}e^{i\pi(\omega_1k_1^2+\omega_2k_2^2+2\omega k_1k_2)}e^{2i\pi(k_1\theta_1+k_2\theta_2)} \tag{4.1.1}$$

where $\vec{q} = (q_1, q_2)$ and $\Omega \in M(]0,1[)_{sym}$ with

$$\Omega = \begin{bmatrix} \omega_1 & \omega \\ \omega & \omega_2 \end{bmatrix} \tag{4.1.2}$$

$A_{\vec{q}}$ labels integer sites of rectangles of dimensions $q_1 \times q_2$. We first assume that $0 < \omega q_1 + \theta_1 < 1$ and $0 < \omega q_2 + \theta_2 < 1$. As q_1 and q_2 are to be large numbers, one may call these matrices *weak coupling* matrices. If $\omega = 0$, this Gaussian sum goes back to a product of one-dimensional Gaussian sums. In general:

$${}^2\sigma^{[0,0]}_{A_{\vec{q}}}(\Omega, \vec{\theta}) = \sum_{k_1=0}^{q_1-1} e^{i\pi(\omega_1 k_1^2 + 2\theta_1 k_1)} \sum_{k_2=0}^{q_2-1} e^{i\pi(\omega_2 k_2^2 + 2\omega k_1 k_2 + 2\theta_2 k_2)} \tag{4.1.3}$$

We shall establish the duality formula successively with respect to $(k_1,\, k_2)$. If the duality transformation is performed on the k_2 sum one gets:

$$\begin{aligned}
{}^2\sigma^{[0,0]}_{A_{\vec{q}}}(\Omega, \vec{\theta}) \quad &= \quad \sum_{k_1=0}^{q_1-1} e^{i\pi(w_1 k_1^2 + 2\theta_1 k_1)} e^{-i\pi \frac{(\omega k_1 + \theta_2)^2}{\omega_2}} \\
&\quad\quad \sqrt{\frac{i}{\omega_2}} \left(\sum_{k_2=0}^{\omega_2(q_2-1)} e^{-i\pi \frac{k_2^2}{\omega_2}} e^{2i\pi \frac{(\omega k_1 + \theta_2)^2}{\omega_2}} + \mathcal{O}(1) \right) \\
&= \quad \sqrt{\frac{i}{\omega_2}} e^{-i\pi \frac{\theta_2^2}{\omega_2}} \left(\sum_{k_2=0}^{\omega_2(q_2-1)} e^{-i\pi \frac{k_2^2}{\omega_2}} e^{2i\pi \frac{\theta_2}{\omega_2} k_2} e^{2i\pi(\theta_1 - \theta_2 \frac{\omega}{\omega_2} + \frac{\omega}{\omega_2} k_2) k_1} \right. \\
&\quad\quad \left. \sum_{k_1=0}^{q_1-1} e^{i\pi \frac{\omega_1 \omega_2 - \omega^2}{\omega_2} k_1^2} \right) \\
&+ \quad \mathcal{O}(1) \sqrt{\frac{i}{\omega_2}} e^{-i\pi \frac{\theta_2^2}{\omega_2}} \sum_{k_1=0}^{q_1-1} e^{i\pi \frac{\omega_1 \omega_2 - \omega^2}{\omega_2} k_1^2} e^{2i\pi(\theta_1 - \frac{\omega}{\omega_2} \theta_2) k_1}
\end{aligned} \tag{4.1.4}$$

when Ω is invertible matrix $(\det(\Omega) \neq 0)$, we can apply further the duality transformation on the k_1 sum and obtain:

$$\begin{aligned} {}^2\sigma^{[0,0]}_{A_{\vec{q}}}(\Omega,\vec{\theta}) &= \sqrt{\frac{i}{\omega_2}} e^{-i\pi\frac{\theta_2^2}{\omega_2}} \left(\sum_{k_2=0}^{\omega_2 q_2 - 1} e^{-i\pi\left(\frac{k_2^2}{\omega_2}+2\frac{\theta_2^2}{\omega_2}k_2\right)} e^{-i\pi\frac{\omega_2\theta_2-\omega\theta_2+\omega k_2}{\omega_2(\omega_1\omega_2-\omega^2)}k_1} \right) \\ &\times \left(\sum_{k_1=0}^{\left(\omega_1-\frac{\omega^2}{\omega_2}\right)q_1-1} e^{-i\pi\frac{\omega_2}{\omega_1\omega_2-\omega^2}k_1^2} e^{2i\pi\frac{\omega_2\theta_1-\omega\theta_2+\omega k_2}{\omega_2(\omega_1\omega_2-\omega^2)}k_1} \right) \\ &+ \mathcal{O}(1)\sqrt{\frac{i}{\omega_2}} e^{-i\pi\frac{\theta_2^2}{\omega_2}} e^{-i\pi\frac{\omega_2}{\omega_1\omega_2-\omega^2}(\theta_2-\frac{\omega}{\omega_2}\theta_1)} \qquad (4.1.5) \\ &\times \left(\sum_{k_2=0}^{\left(\omega_1-\frac{\omega^2}{\omega_2}\right)q_2-1} e^{-i\pi\frac{\omega_2}{\omega_1\omega_2-\omega^2}k_1^2} e^{2i\pi\frac{\omega_2\theta_2-\omega\theta_2}{\omega_2(\omega_1\omega_2-\omega^2)}k_1} + \mathcal{O}(1) \right) \end{aligned}$$

Now taking into account the assumptions on ω, the summation over the variable k_1 from 0 to $\left(\omega_1 - \frac{\omega^2}{\omega_2}\right) q_1 - 1$ is the same as the summation on $k_1 = 0, \ldots, \omega_1 q_1 - 1$. This fact occurs also for the k_2 such that the above expression becomes:

$$\begin{aligned} {}^2\sigma^{[0,0]}_{A_{(q_1,q_2)}}(\Omega,\vec{\theta}) = \frac{ie^{-i\pi\, {}^t\vec{\theta}\Omega^{-1}\vec{\theta}}}{\sqrt{det(\Omega)}} \Big[{}^2\sigma^{[0,0]}_{A_{(\omega_1 q_1,\omega_2 q_2)}}(-\Omega^{-1},\Omega^{-1}\vec{\theta}) + \qquad (4.1.6) \\ \mathcal{O}(1)\left({}^2\sigma^{[0,0]}_{\mathcal{P}_1[A_{(\omega_1 q_1,\omega_2 q_2)}]}(-\Omega^{-1},\Omega^{-1}\vec{\theta}) + {}^2\sigma^{[0,0]}_{\mathcal{P}_2[A_{(\omega_1 q_1,\omega_2 q_2)}]}(-\Omega^{-1},\Omega^{-1}\vec{\theta}) + 1 \right) \Big] \end{aligned}$$

where $\mathcal{P}_1$, (resp. $\mathcal{P}_2$) is the projection onto the plane $\{k_1 = 0\}$ (resp. $\{k_2 = 0\}$). We notice also that the duality transformation replaces essentially sums over k by other sums over k with an error of order 1. For example $\sum_{k_1,k_2}$ is replaced by $(\sum_{k_1} + \mathcal{O}(1))\,(\sum_{k_2} + \mathcal{O}(1)) \simeq \sum_{k_1,k_2} + \mathcal{O}(1)\sum_{k_1} + \mathcal{O}(1)\sum_{k_2} + \mathcal{O}^2(1)$. Moreover, there is a simplification since

$${}^2\sigma^{[0,0]}_{\mathcal{P}_1[A(\omega q_1,\omega_2 q_2)]}(-\Omega^{-1},\Omega^{-1}\vec{\theta}) = {}^1\sigma^{[0]}_{A(\omega_2 q_2)}\left(-\frac{\omega_1}{\omega_1\omega_2-\omega^2}, \frac{\omega_1\theta_2-\omega\theta_1}{\omega_1\omega_2-\omega^2}\right) \qquad (4.1.7)$$

For sufficiently small ω, integer sites such that $0 \leq k_1 \leq \omega_1 q_1$ and $0 \leq k_2 \leq$

$\omega_2 q_2$ are those with $\vec{k} = (k_1, k_2) \in \Omega(A_{\vec{q}})$. Thus:

$$\begin{aligned} {}^2\sigma^{[0,0]}_{A_{\vec{q}}}(\Omega, \vec{\theta}) &= \frac{ie^{-i\pi\, {}^t\vec{\theta}\Omega^{-1}\vec{\theta}}}{\sqrt{det(\Omega)}} \Big[{}^2\sigma^{[0,0]}_{\Omega A_{\vec{q}}}(-\Omega^{-1}, \Omega^{-1}\vec{\theta}) + \mathcal{O}(1).{}^2\sigma^{[0,0]}_{\mathcal{P}_1[\Omega A_{\vec{q}}]}(-\Omega^{-1}, \Omega^{-1}\vec{\theta}) \\ &+ \mathcal{O}(1).{}^2\sigma^{[0,0]}_{\mathcal{P}_2[\Omega A_{\vec{q}}]}(-\Omega^{-1}, \Omega^{-1}\vec{\theta}) + \mathcal{O}(1) \Big] \end{aligned} \tag{4.1.8}$$

Now for $\vec{a}$ and $\vec{b}$ non zero (i.e. $a_i = \{0, 1\}; b_i = \{0, 1\}$, $i = 1, 2$), we have in a similar manner the lemma

Lemma 8 $\forall \Omega \in M_2(I\!R)_{sym}$ *an invertible matrix and with* ω *small enough:*

$$\begin{aligned} {}^2\sigma^{[\vec{a},\vec{b}]}_{A_{\vec{q}}}(\Omega, \vec{\theta}) &= \frac{ie^{-i\pi\, {}^t\vec{\theta}\Omega^{-1}\vec{\theta}}}{\sqrt{det(\Omega)}} [{}^2\sigma^{[\vec{b},\vec{a}]}_{\Omega A_{\vec{q}}}(-\Omega^{-1}\Omega^{-1}, \vec{\theta}) + \mathcal{O}(1).{}^2\sigma^{[\vec{b},\vec{a}]}_{\mathcal{P}_1[\Omega A_{\vec{q}}]}(-\Omega^{-1}\Omega^{-1}, \vec{\theta}) \\ &+ \mathcal{O}(1).{}^2\sigma^{[\vec{b},\vec{a}]}_{\mathcal{P}_2[\Omega A_{\vec{q}}]}(-\Omega^{-1}\Omega^{-1}, \vec{\theta}) + \mathcal{O}(1)]. \end{aligned} \tag{4.1.9}$$

where ${}^2\sigma^{[\vec{a},\vec{b}]}_{A_{\vec{q}}}(\Omega, \vec{\theta}) = \sum_{\vec{k}\in A_{\vec{q}}} e^{i\pi^t(\vec{k}-\frac{\vec{a}}{2})\Omega(\vec{k}-\frac{\vec{a}}{2})} e^{2\pi i^t(\vec{\theta}-\frac{\vec{b}}{2})(\vec{k}-\frac{\vec{a}}{2})}$.

4.2 Two-dimensional Gaussian sums with degenerate matrix Ω

In the expression of ${}^2\sigma^{[0,0]}_{A_{\vec{q}}}(\Omega, \vec{\theta})$ see Eq 4.1.1 we perform the duality transformation on k_2 sums. This operation yields:

$$\begin{aligned} {}^2\sigma^{[0,0]}_{A_{\vec{q}}}(\Omega, \vec{\theta})) &= \sqrt{\frac{i}{\omega_2}} e^{-i\pi\frac{\theta_2^2}{\Omega_2}} e^{i\pi(q-1)(\theta_1 - \frac{\omega}{\omega_2}\theta_2)} \left(\sum_{k_2=0}^{\omega_2 q_2 - 1} e^{-i\pi\frac{k_2^2}{\omega_2}} e^{2i\pi(\frac{\theta_2}{\omega_2} + \frac{(q-1)\omega}{2\omega_2})k_2} \right. \\ & \left. \frac{\sin \pi q_1 \left(\theta_1 - \frac{\omega}{\omega_2}(k_2 - 1)\right)}{\sin \pi \left(\theta_1 - \frac{\omega}{\omega_2}(k_2 - 1)\right)} + \mathcal{O}(1) \frac{\sin \pi q_1 \left(\theta_1 - \frac{\omega}{\omega_2}\right)}{\sin \pi \left(\theta_1 - \frac{\omega}{\omega_2}\right)} \right) \end{aligned} \tag{4.2.1}$$

We observe that for Ω non invertible, the general form of the sum $e^{i\pi\, quadratic\ form}.e^{i\pi\, linear\ form}$ is not preserved under this duality transformation. Moreover the symmetry $k_1 \leftrightarrow k_2$ seems to be apparently broken since its expression depends on which variable to be transformed first by duality. This type of formula will be used later on, although with an appropriate form.

In the present case, it is sufficient to perform successive dualities uniquely on the variable k_2 until the summation on k_2 is equal to $\mathcal{O}(1)$. Then perform at last the geometric summation over k_1. We shall now remove the restriction to small ω and consider the general case. Let us give the following definition:

Definition 9 *An invertible symmetric matrix is called non-diagonal integer, when there are no integer entries outside its diagonal. This set of such matrices is denoted by* $M^*_{\mathbb{Z}}(\mathbb{R})_{inv,sym}$

Let

$$f_{[\Omega,\vec{\theta}]}(\vec{k}+\vec{n}) = e^{i\pi\,{}^t(\vec{k}+\vec{n})\Omega(\vec{k}+\vec{n})}e^{2i\pi\,{}^t(\vec{k}+\vec{n})\vec{\theta}} \tag{4.2.2}$$

with $\vec{\theta}' \equiv \vec{\theta}+\Omega\vec{n} \mod 1$, we have

$$\begin{aligned} f_{[\Omega,\vec{\theta}]}(\vec{k}+\vec{n}) &= e^{2\pi i\,{}^t\vec{k}\Omega\vec{n}}f_{[\Omega,\vec{\theta}]}(\vec{k})f_{[\Omega,\vec{\theta}]}(\vec{n}) \\ &= f_{[\Omega,\vec{\theta}]}(\vec{n})f_{[\Omega,\vec{\theta}']}(\vec{k}) \end{aligned} \tag{4.2.3}$$

So for θ_1 and θ_2 given, let (q_1', q_2') such that the duality formula is valid, we cut the domain $\{0 \leq k_1 < q_1,\, 0 \leq k_2 < q_2\}$ into small rectangles of size $q_1' \times q_2'$. Let us consider the set:

$$\begin{aligned} B(m_1,m_2) &= \big\{(k_1,k_2) \in \mathbb{N}^2 \quad | \quad m_1q_1' \leq k_1 < (m_1+1)q_1' \quad \text{and} \\ &\qquad m_2q_2' \leq k_2 < (m_2+1)q_2'\big\} \end{aligned} \tag{4.2.4}$$

Necessarily $m_1 \leq e(q_1/q_1')$ and $m_2 \leq e(q_2/q_2')$; here $e(q/q')$ represents the integer part of q/q'. It is sufficient to verify that the duality formula is proved by pasting together the $B(m_1,m_2)$. Call $\vec{m} = (m_1,m_2)$. Then

$$\begin{aligned} \sum_{\vec{k}\in B(\vec{m})} f_{[\Omega,\vec{\theta}]}(\vec{k}) &= \sum_{\vec{k}\in B(\vec{0})} f_{[\Omega,\vec{\theta}]}(\vec{k}+\vec{m})] \\ &= f_{[\Omega,\vec{\theta}]}(\vec{m}) \sum_{\vec{k}\in\Omega B(\vec{0})} f_{[\Omega,\vec{\theta}'']}(\vec{k}) \end{aligned} \tag{4.2.5}$$

with $\vec{\theta}'' = \vec{\theta}+\Omega\vec{m}-\vec{N}$, where $\vec{N}$ is a vector with integer coordinates such that $\forall i$, $\theta_i'' = \theta_i + (\Omega\vec{m})_i - N_i \in]0,1[$. Now we perform the duality transformation

:

$$\sum_{\vec{k}\in B(\vec{m})} f_{[\Omega,\vec{\theta}]}(\vec{k}) = f_{[\Omega,\vec{\theta}]}(\vec{m}) i \frac{e^{-i\pi{}^t\vec{\theta}'\Omega^{-1}\vec{\theta}'}}{\det(\Omega)} \left[\sum_{\vec{k}\in\Omega B(\vec{0})} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}'']}(\vec{k}) \right. \tag{4.2.6}$$
$$\left. +\mathcal{O}(1)\left(\sum_{\vec{k}\in\mathcal{P}_1\Omega B(\vec{0})} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}'']}(\vec{k}) + \sum_{\vec{k}\in\mathcal{P}_2\Omega B(\vec{0})} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}'']}(\vec{k}) + 1 \right) \right]$$

with

$$e^{i\pi{}^t\vec{\theta}'\Omega\vec{\theta}'} = e^{i\pi{}^t\vec{\theta}\Omega^{-1}\vec{\theta}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{N}) f_{[-\Omega,-\vec{\theta}]}(\vec{m}) \tag{4.2.7}$$

since ${}^t\vec{N}\cdot\vec{m}\in\mathbb{N}$. Finally:

$$\sum_{\vec{k}\in B(\vec{m})} f_{[\Omega,\vec{\theta}]}(\vec{k}) = i \frac{e^{-i\pi{}^t\vec{\theta}\Omega^{-1}\vec{\theta}}}{\sqrt{\det(\Omega)}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{N}) \left[\sum_{\substack{\vec{k}\in\\ \Omega B(\vec{0})}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}-\Omega^{-1}\vec{N}]}(\vec{k}) \right.$$
$$\left. +\mathcal{O}(1)\left(\sum_{\substack{\vec{k}\in\\ \mathcal{P}_1\Omega B(\vec{0})}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}-\Omega^{-1}\vec{N}]}(\vec{k}) + \sum_{\substack{\vec{k}\in\\ \mathcal{P}_2\Omega B(\vec{0})}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}-\Omega^{-1}\vec{N}]}(\vec{k}) + 1 \right) \right] \tag{4.2.8}$$

or alternatively:

$$\sum_{\vec{k}\in B(\vec{m}} f_{[\Omega,\vec{\theta}]}(\vec{k}) = i \frac{e^{-i\pi{}^t\vec{\theta}\Omega\vec{\theta}}}{\det(\Omega)} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{N}) \left[\sum_{\substack{(\vec{k}-\vec{N})\in\\ \Omega B(\vec{0})}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{N}) \right.$$
$$\left. +\mathcal{O}(1)\left(\sum_{\substack{(\vec{k}-\vec{N})\in\\ \mathcal{P}_1\Omega B(\vec{0})}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}}(\vec{k}) + \sum_{\substack{(\vec{k}-\vec{N})\in\\ \mathcal{P}_2\Omega B(\vec{0})}} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{k}) + 1 \right) \right] \tag{4.2.9}$$

Here $\vec{N}$ is an integer vector such that $\forall i = 1,2,\ |N_i - (\Omega\vec{m})_i| < 1$. Thus replacing $\vec{N}$ by $\Omega\vec{m}$ we make an error in the double sum $\sum_{k_1,k_2}$ of the order

$\mathcal{O}(1)\sum_{k_1}$ and $\mathcal{O}(1)\sum_{k_2}$ and an error in respect to the $\sum_{k_1}$ (resp. $\sum_{k_1}$) of order $\mathcal{O}(1)$. The index $(\vec{k}-\Omega\vec{m}) \in \Omega B(\vec{0})$ is equivalent to $\vec{k} \in \Omega(\vec{m}-B(\vec{0}))$ or also $\vec{k} \in \Omega B(\vec{m}))$ by linearity. For the same reasons we have, for $i=1,2$, $(\vec{k}-\Omega\vec{m}) \in \mathcal{P}(\Omega B(\vec{0}))$ is equivalent to $\vec{k} \in \mathcal{P}(\Omega B(\vec{m}))$ and we have:

$$\begin{aligned}
&\sum_{k_1=0}^{q_1-1}\sum_{k_2=0}^{q_2-1} f_{[\Omega,\vec{\theta}]}(\vec{k}) = \sum_{r=0}^{e(q_1/q_1')}\sum_{s=0}^{e(q_2/q_2')}\sum_{\vec{k}\in B(r,s)} f_{[\Omega,\vec{\theta}]}(\vec{k}) i\frac{e^{-i\pi^t\vec{\theta}\Omega\vec{\theta}}}{\sqrt{\det(\Omega)}}\sum_{r=0}^{e(q_1/q_1')}\sum_{s=0}^{e(q_2/q_2')} \\
&= \left[\sum_{\vec{k}\in\Omega B(r,s)} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{k})\right. \\
&\left.+\mathcal{O}(1)\left(\sum_{\vec{k}\in\mathcal{P}_1\Omega B(r,s)} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{k}) + \sum_{\vec{k}\in\mathcal{P}_2\Omega B(r,s)} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{k})+1\right)\right] \\
&= i\frac{e^{-i\pi^t\vec{\theta}\Omega\vec{\theta}}}{\det(\Omega)}\left[\sum_{\vec{k}\in\Omega A(q_1,q_2)} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{k})\right. \qquad (4.2.10) \\
&\left.+\mathcal{O}(1)\left(\sum_{\vec{k}\in\mathcal{P}_1\Omega A(q_1,q_2)} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{k}) + \sum_{\vec{k}\in\mathcal{P}_2\Omega A(q_1,q_2)} f_{[-\Omega^{-1},\Omega^{-1}\vec{\theta}]}(\vec{k})+1\right)\right]
\end{aligned}$$

Finally the same calculation shows that for all bounded domains $\mathcal{D} \in \mathbb{N}^2$, we have the theorem

Theorem 4.1 (Duality) *Let* $\Omega \in M_2^*(]0,1[)_{inv}$, $\mathcal{D}$ *the bounded domain in* $\mathbb{N}^2$ *we have:*

$$\begin{aligned}
&{}^2\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega,\vec{\theta}) = i\frac{e^{-i\pi^t\vec{\theta}\Omega\vec{\theta}}}{\det(\Omega)}\left[{}^2\sigma_{\Omega\mathcal{D}}^{[\vec{a},\vec{b}]}(-\Omega^{-1},\Omega^{-1}\vec{\theta}) + \mathcal{O}(1).{}^2\sigma_{\mathcal{P}_1(\Omega\mathcal{D})}^{[\vec{a},\vec{b}]}(-\Omega^{-1},\Omega^{-1}\vec{\theta})\right. \\
&\left.+\mathcal{O}(1).{}^2\sigma_{\mathcal{P}_2(\Omega\mathcal{D})}^{[\vec{a},\vec{b}]}(-\Omega^{-1},\Omega^{-1}\vec{\theta}) + \mathcal{O}(1)\right]
\end{aligned} \qquad (4.2.11)$$

This formula can be extended to the set of matrices $\Omega \in M_2^*(\mathbb{R})_{inv}$. This result is given in the next section where the general case with d dimensions is treated.

5 d-dimensional Gaussian sums: Generalizations

In this section, proofs or parts of proofs that are similar to those in two dimensions will not be repeated. Let us consider the case where non-diagonal elements ω_{ij}, $(i \neq j)$ are sufficiently small for the same vector $\vec{\theta}$, and where Ω is invertible. We shall study the case $\vec{a} = \vec{b} = \vec{0}$. The general case can be deduced by analogy. Performing the dual transformation on only one variable k_m with $1 \leq m \leq d$ on the sum defining:

$$
\begin{aligned}
{}^{d}\sigma^{[\vec{0},\vec{0}]}_{A_{\vec{q}}}(\Omega,\vec{\theta}) &= \sum_{k_1=0}^{q_1-1}\cdots\sum_{k_d=0}^{q_d-1} e^{i\pi[\sum_{1\leq i\leq d}\omega_{ii}k_i^2+2\sum_{1\leq i<j\leq d}\omega_{ij}k_ik_j+2\sum_{1\leq i\leq d}k_i\theta_i]} \\
= \ & \sum_{k_1=0}^{q_1-1}\cdots\sum_{k_m=0}^{\omega_{m,m}q_m-1}\cdots\sum_{k_d=0}^{q_d-1} e^{i\pi[\sum_{1\leq i\leq d}^{i\neq m}\omega_{ii}k_i^2+2\sum_{1\leq i<j\leq d}^{i\neq m,\, j\neq m}\omega_{ij}k_ik_j+2\sum_{1\leq i\leq d}^{i\neq m}k_i\theta_i]} \\
\times \ & \sum_{k_m=0}^{q_m-1} e^{i\pi[\omega_{mm}k_m^2+2(\theta_m+\sum_{1\leq i\leq d}\omega_{mi}k_i)k_m]}
\end{aligned}
\tag{5.0.1}
$$

We get:

$$
\begin{aligned}
{}^{d}\sigma^{[\vec{0},\vec{0}]}_{A_{\vec{q}}}(\Omega,\vec{\theta}) \ = \ & \sum_{k_1=0}^{q_1-1}\cdots\sum_{\hat{k}_m=0}^{q_m-1}\cdots\sum_{k_d=0}^{q_d-1} e^{i\pi[\sum_{1\leq i\leq d}^{i\neq m}\omega_{ii}k_i^2+2\sum_{1\leq i<j\leq d}^{i\neq m,\, j\neq m}\omega_{ij}k_ik_j} \\
\times \ & e^{2\sum_{1\leq i\leq d}^{i\neq m}k_i\theta_i}\sqrt{\frac{i}{\omega_{mm}}}\sum_{k_i\neq k_m} e^{-\frac{\pi}{\omega_{mm}}(\theta_m+\sum_{1\leq i\leq d}\omega_{mi}k_i)^2} \\
\times \ & \left(\sum_{k_m=0}^{\omega_m q_m-1} e^{i\pi[-\frac{k_m^2}{\omega_{mm}}+2(\theta_m+\sum_{1\leq i\leq d}\omega_{mi}k_i)\frac{k_m}{\omega_{mm}}]} + \mathcal{O}(1)\right)
\end{aligned}
\tag{5.0.2}
$$

Let us define D_m as the dual transformation operator on the index k_m. We observe that for any function f:

$$
\mathcal{O}_m(1)f(\ldots,k_m,\ldots) = \mathcal{O}(1)f(\ldots,k_m=0,\ldots) \tag{5.0.3}
$$

Thus regrouping terms using the previous remark, we have:

$$\begin{aligned}
{}^{d}\sigma_{A_{\vec{q}}}^{[\vec{a},\vec{b}]}(\Omega,\vec{\theta}) &= \sqrt{\frac{i}{\omega_{mm}}}e^{-i\pi\frac{\theta_m^2}{\omega_{mm}}}\sum_{k_1=0}^{q_1-1}\cdots\left(\sum_{k_m=0}^{\omega_{mm}q_m-1}+\mathcal{O}_m(1)\right)\cdots \\
&\quad \sum_{k_d=0}^{q_d-1}e^{-i\pi\left(\frac{k_m^2}{\omega_{mm}}-\sum_{i\neq m}(\omega_{ii}-\frac{\omega_{mi}^2}{\omega_{mm}})k_i^2\right)} \qquad (5.0.4)\\
&\times \quad e^{i\pi\sum_{1\leq i<j\leq d}^{i\neq m,\, j\neq m}(\omega_{ij}-\frac{\omega_{mi}\omega_{mj}}{\omega_{mm}})k_ik_j}e^{i\pi\sum_{1\leq i\leq d}^{i\neq m}\frac{\omega_{mi}}{\omega_{mm}}k_ik_m} \\
&\times \quad e^{2i\pi\sum_{1\leq i\leq d}^{i\neq m}(\theta_1-\frac{\omega_{mi}}{\omega_{mm}}\theta_m)k_i}e^{2i\pi\sum_{1\leq i\leq d}^{i\neq m}\frac{\theta_m}{\omega_{mm}}k_m}
\end{aligned}$$

Now this relation may be reexpressed using the dualization with respect to the variable k_m, $\mathcal{D}_m$, defined by:

$$\begin{aligned}
&\mathcal{D}_m\left(\sum_{k_1=0}^{q_1-1}\cdots\sum_{k_d=0}^{q_d-1}e^{i\pi[\sum_{1\leq i\leq d}\omega_{ii}k_i^2+2\sum_{1\leq i<j\leq d}\omega_{ij}k_ik_j+2\sum_{1\leq i\leq d}k_i\theta_i]}\right)= \\
&\Phi'\sum_{k_1=0}^{q_1-1}\cdots\left(\sum_{k_m=0}^{\omega_{mm}q_m-1}+\mathcal{O}_m(1)\right)\cdots\sum_{k_d=0}^{q_d-1}e^{i\pi[\sum_{1\leq i\leq d}\omega'_{ii}k_i^2} \\
\times\quad &e^{+2\sum_{1\leq i<j\leq d}\omega'_{ij}k_ik_j+2\sum_{1\leq i\leq d}k_i\theta'_i]} \qquad (5.0.5)
\end{aligned}$$

Thus under the action of $\mathcal{D}_m$, matrix elements of Ω, $\vec{\theta}$ are transformed and a multiplicative factor is introduced, leading to the following relations :

- $\omega'_{ij}=\omega_{ij}-\frac{\omega_{im}\omega_{jm}}{\omega_{mm}}$, $\forall 1\leq i\leq d$, $\forall 1\leq j\leq d$ with $i\neq m$ and $j\neq m$
- $\omega'_{mm}=-\frac{1}{\omega_{mm}}$,
- $\theta'_i=\theta_i-\frac{\omega_{im}}{\omega_{mm}}\theta_m$ $\forall 1\leq i\leq d$, with $i\neq m$
- $\theta'_m=\frac{\theta_m}{\omega_{mm}}$
- $\Phi'=\sqrt{\frac{i}{\omega_{mm}}}e^{-i\pi\frac{\theta_m^2}{\omega_{mm}}}\Phi$ with $\Phi=1$

and of course we have $\Omega'=\mathcal{D}_m(\Omega)$, $\vec{\theta'}=\mathcal{D}_m(\theta)$ and $\Phi'=\mathcal{D}_m(\Phi)$. Under the action of duality on the index k_m the matrix Ω becomes a symmetric matrix. So let us apply this transformation successively as follows, $1 \leq m \leq d$.

$$\begin{bmatrix} \Omega \\ \vec{\theta} \\ 1 \end{bmatrix} = \begin{bmatrix} \Omega_0 \\ \vec{\theta}_0 \\ \Phi_0 \end{bmatrix} \underset{\mathcal{D}_1}{\longmapsto} \begin{bmatrix} \Omega_1 \\ \vec{\theta}_1 \\ \Phi_1 \end{bmatrix} \underset{\mathcal{D}_2}{\longmapsto} \dots \underset{\mathcal{D}_m}{\longmapsto} \begin{bmatrix} \Omega_m \\ \vec{\theta}_m \\ \Phi_m \end{bmatrix} \tag{5.0.6}$$

where each bracket represents, with the set $[\Omega, \vec{\theta}, \Phi]$ the effect of the transformation. Define now the symmetric matrix B_m taken from Ω as:

$$B_m = \begin{bmatrix} \omega_{11} & \dots & \omega_{1m} \\ \vdots & & \vdots \\ \omega_{m1} & \dots & \omega_{mm} \end{bmatrix} \tag{5.0.7}$$

$$\Phi_m = \frac{\sqrt{i}^m}{\sqrt{\det B_m}} e^{-i\pi.{}^t(\theta_1,\dots,\theta_m)B_m^{-1}(\theta_1,\dots,\theta_m)} \tag{5.0.8}$$

with for $1 \leq i \leq m$ and $1 \leq j \leq m$

$$(\omega_{m+1})_{i,j} = \frac{(-1)^{i+j}}{\det B_m} \det \begin{bmatrix} \omega_{11} & \dots & \omega_{1,j-1} & \omega_{1,j+1} & \dots & \omega_{1,m} \\ \vdots & & \vdots & \vdots & & \vdots \\ \omega_{i-1,1} & \dots & \omega_{i-1,j-1} & \omega_{i-1,j+1} & \dots & \omega_{i-1,m} \\ \omega_{i+1,1} & \dots & \omega_{i+1,j-1} & \omega_{i+1,j+1} & \dots & \omega_{i+1,m} \\ \vdots & & \vdots & \vdots & & \vdots \\ \omega_{m,1} & \dots & \omega_{m,j-1} & \omega_{m,j+1} & \dots & \omega_{m,m} \end{bmatrix} \tag{5.0.9}$$

that is essentially the (i,j) cofactor of B_m . In a more compact way we can write

$$\Omega_{m+1}|_{(i,j)=1\dots,m} = -B_m^{-1} \tag{5.0.10}$$

for $m < i$ and $1 \leq j \leq m$

$$(\omega_{m+1})_{i,j} = \frac{1}{\det B_m} \det \begin{bmatrix} \omega_{11} & \dots & \omega_{1,j-1} & \omega_{1i} & \omega_{1,j+1} & \dots & \omega_{1,m} \\ \vdots & & \vdots & \vdots & \vdots & & \vdots \\ \omega_{m,1} & \dots & \omega_{m,j-1} & \omega_{mi} & \omega_{m,j+1} & \dots & \omega_{m,m} \end{bmatrix} \tag{5.0.11}$$

This is obtained by substitution of the j^{th} column by the i^{th} line. Hence if $m < i$ and $m < j$, we have:

$$(\omega_{m+1})_{i,j} = \frac{1}{\det B_m} \det \begin{bmatrix} \omega_{11} & \dots & \omega_{1,m} & \omega_{i,j} \\ \vdots & & \vdots & \vdots \\ \omega_{m1} & \dots & \omega_{m,m} & \omega_{m,j} \\ \omega_{i1} & \dots & \omega_{i,m} & \omega_{i,j} \end{bmatrix} \tag{5.0.12}$$

The right hand side is a $(m+1) \times (m+1)$ matrix obtained from B_m having a piece of the i^{th} line and j^{th} column with $m < i$ and $m < j$. Finally

$$\begin{bmatrix} \theta_1^m \\ \vdots \\ \theta_m^m \end{bmatrix} = B_m^{-1} \begin{bmatrix} \theta_1 \\ \vdots \\ \theta_m \end{bmatrix} \tag{5.0.13}$$

and for all $i > m$

$$\theta_i^m = \theta_i + \sum_{j=1}^{m} (\omega_{m+1})_{ij} \theta_j \tag{5.0.14}$$

These results may be proven by recursion. The proof is uniquely based on the expansion of the determinant into minors. For example for $(\omega_{m+1})_{11}$, one has to compute:

$$(\omega_m)_{11} - \frac{(\omega_m)_{1m}^2}{(\omega_m)_{mm}} \tag{5.0.15}$$

with

- $$(\omega_m)_{11} = \frac{(\tilde{B}_m)_{11}}{\det B_m} \tag{5.0.16}$$

  where $\tilde{B}_m$ is the matrix formed by cofactors of B_m

- $$(\omega_m)_{mm} = \frac{\det B_{m+1}}{\det B_m} \tag{5.0.17}$$

  with $\det B_{m+1} = \omega_{m+1,m+1} \det B_m + \sum_{i=1}^{m} \sum_{j=1}^{m} \omega_{i,m+1} \omega_{m+1,j} (\tilde{B}_m)_{i,j}$

- $$(\omega_m)_{im} = \sum_{i=1}^{m} \omega_{i,m+1} \frac{(\tilde{B}_m)_{i,1}}{\det B_m} \tag{5.0.18}$$

Hence

$$(\omega_m)_{11} - \frac{(\omega_m)_{1m}^2}{(\omega_m)_{mm}} = \frac{\omega_{m+1,m+1}(\tilde{B}_m)_{11}}{\det B_{m+1}} \tag{5.0.19}$$
$$+\frac{1}{\det B_{m+1} \det B_m} \sum_{i=1}^{m} \sum_{j=1}^{m} \omega_{i,m+1}\omega_{m+1,j} \left((\tilde{B}_m)_{11}(\tilde{B}_m)_{ij} - (\tilde{B}_m)_{1j}(\tilde{B}_m)_{i1} \right)$$

Knowing that the determinant is invariant (up to a sign) under permutations of lines or columns, it is sufficient to compute:

$$(\tilde{B}_m)_{11}(\tilde{B}_m)_{mm} - (\tilde{B}_m)_{1m}(\tilde{B}_m)_{m1} = \left(\sum_{\sigma \in \mathcal{S}_{m-1}} (-1)^{\epsilon(\sigma)} \prod_{i=1}^{m-1} \omega_{i+1,\sigma(i)+1} \right)$$
$$\left(\sum_{\sigma' \in \mathcal{S}_{m-1}} (-1)^{\epsilon(\sigma')} \prod_{i=1}^{m-1} \omega_{i,\sigma'(i)} \right) - \left(\sum_{\sigma \in \mathcal{S}_{m-1}} (-1)^{\epsilon(\sigma')} \prod_{i=1}^{m-1} \omega_{i,\sigma(i)+1} \right)$$
$$\left(\sum_{\sigma' \in \mathcal{S}_{m-1}} (-1)^{\epsilon(\sigma)} \prod_{i=1}^{m-1} \omega_{i+1,\sigma'(i)} \right) \tag{5.0.20}$$

Where $\mathcal{S}_{m-1}$ is the symmetric group of permutations of order $(m-1)$. After expansion and regrouping, we get the double sum:

$$\sum_{\sigma \in \mathcal{S}_{m-1}} \sum_{\sigma' \in \mathcal{S}_{m-1}} (-1)^{\epsilon(\sigma)+\epsilon(\sigma')} \prod_{i=1}^{m-1} \prod_{j=1}^{m-1} \left(\omega_{i+1,\sigma(i)+1}\omega_{j,\sigma(j)} - \omega_{i,\sigma(i)+1}\omega_{j+1,\sigma(j)} \right) \tag{5.0.21}$$

Now the product of permutations $\sigma \otimes \sigma' \in \mathcal{S}_{m-1} \times \mathcal{S}_{m-1}$ may be represented as $\sigma \otimes \sigma' \in \mathcal{S}_m \times \mathcal{S}_{m-2}$ and the previous double sum is recast under the form:

$$\begin{aligned}
&\sum_{\sigma\in\mathcal{S}_m}\sum_{\sigma'\in\mathcal{S}_{m-2}}(-1)^{\epsilon(\sigma)+\epsilon(\sigma')}\prod_{i=1}^{m}\prod_{j=1}^{m-2}\left(\omega_{i,\sigma(i)}\omega_{j+1,\sigma(j)+1}\right) \qquad (5.0.22)\\
=\ &\left(\sum_{\sigma\in\mathcal{S}_m}(-1)^{\epsilon(\sigma)}\prod_{i=1}^{m\omega_{i,\sigma(i)}}\right)\left(\sum_{\sigma\in\mathcal{S}_{m-2}}(-1)^{\epsilon(\sigma)}\prod_{i=1}^{m-2}\omega_{i+1,\sigma(i)+1}\right)\\
=\ &\det B_m \det\begin{bmatrix} \omega_{12} & \dots & \omega_{1,m-1}\\ \vdots & & \vdots\\ \omega_{m-1,2} & \dots & \omega_{m-1,m-1}. \end{bmatrix}
\end{aligned}$$

For opposite permutations of lines and columns we have the following relation:

$$(\tilde{B}_m)_{ij}(\tilde{B}_m)_{kk'} - (\tilde{B}_m)_{ik}(\tilde{B}_m)_{jk'} = \qquad (5.0.23)$$

$$\det B_m \det\begin{bmatrix}
\omega_{11} & \dots & \hat{\omega}_{1,j} & \dots & \hat{\omega}_{1,k'} & \dots & \omega_{1,m}\\
\vdots & & \vdots & & \vdots & & \vdots\\
\hat{\omega}_{i1} & \dots & \hat{\omega}_{i,j} & \dots & \hat{\omega}_{i,k'} & \dots & \hat{\omega}_{i,m}\\
\vdots & & \vdots & & \vdots & & \vdots\\
\hat{\omega}_{k1} & \dots & \hat{\omega}_{k,j} & \dots & \hat{\omega}_{k,k'} & \dots & \hat{\omega}_{k,m}\\
\vdots & & \vdots & & \vdots & & \vdots\\
\omega_{m1} & \dots & \hat{\omega}_{m,j} & \dots & \hat{\omega}_{m,k'} & \dots & \omega_{m,m}
\end{bmatrix} \qquad (5.0.24)$$

The last matrix is of size $(m-2)\times(m-2)$ obtained from B_m by removal of columns j and k' and of the lines i and k . Consequently:

$$(\omega_m)_{11} - \frac{(\omega_m)^2_{1m}}{(\omega_m)_{mm}} = \frac{(\tilde{B}_m)_{11}\omega_{m+1,m+1}}{\det B_{m+1}} + \left(\sum_{i=1}^{m} \sum_{j=1}^{m} \frac{\omega_{i,m+1}\omega_{j,m+1}}{\det B_{m+1}} \det \right.$$
$$\left. \begin{bmatrix} \omega_{11} & \dots & \hat{\omega}_{1,j} & \dots & \hat{\omega}_{1,k'} & \dots & \omega_{1,m} \\ \vdots & & \vdots & & \vdots & & \vdots \\ \hat{\omega}_{i1} & \dots & \hat{\omega}_{i,j} & \dots & \hat{\omega}_{i,k'} & \dots & \hat{\omega}_{i,m} \\ \vdots & & \vdots & & \vdots & & \vdots \\ \hat{\omega}_{k1} & \dots & \hat{\omega}_{k,j} & \dots & \hat{\omega}_{k,k'} & \dots & \hat{\omega}_{k,m} \\ \vdots & & \vdots & & \vdots & & \vdots \\ \omega_{m1} & \dots & \hat{\omega}_{m,j} & \dots & \hat{\omega}_{m,k'} & \dots & \omega_{m,m} \end{bmatrix} \right). \tag{5.0.25}$$

But this expression corresponds to the expansion of the determinant of

$$(\omega_m)_{11} = \frac{(\tilde{B}_{m+1})_{11}}{\det B_{m+1}} = \det \begin{bmatrix} \omega_{22} & \dots & \omega_{2,m+1} \\ \vdots & & \vdots \\ \omega_{m+1,2} & \dots & \omega_{m+1,m+1} \end{bmatrix} \tag{5.0.26}$$

with respect to line $(m+1)$ and column $(m+1)$. Other results may be proved along the same line, i.e. using the expansion of the determinant into minors. Hence if Ω is invertible, one can perform the duality transformation with respect to all indices k_j, and the constants have the expressions:

$$\begin{aligned} \Phi_d &= \frac{\sqrt{i}^d}{\sqrt{\det \Omega}} e^{-i^t\vec{\theta}\Omega^{-1}\vec{\theta}} \\ \Omega_d &= -\Omega^{-1} \\ \vec{\theta}_d &= \Omega^{-1}\vec{\theta} \end{aligned} \tag{5.0.27}$$

Each sum $\sum_{k_i}$ is replaced by $\sum_{k_i} + \mathcal{O}_i(1)$, as seen before. Proceeding as for $d = 2$, one can extend the two-dimensional result to the set of invertible matrices with non-integer diagonal elements. Due to linearity, this formula remains valid for sums on a bounded domain $\mathcal{D} \in \mathbb{Z}^d$. The hypothesis of a bounded domain is necessary since otherwise the Gaussian sums are not converging. This is not the case for theta functions. Consequently, the result is also valid for matrices $\Omega \in M_d(]0,1[)_{inv}$.

There remains the extension to $\mathbb{R} \setminus \mathbb{Z}$ to be examined. For this, let us introduce $L_{ij} \in M_d(\{0,1\})$ such that $(L_{ij})_{k,k'} = 0$ for all k, k' except for

$(k = i, k' = j)$ or $(k = j, k' = i)$. Compute now:

$$\begin{aligned} {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega + L_{ij}, \vec{\theta}) &= \sum_{\vec{k}\in\mathcal{D}} e^{i\pi\left({}^{t}(\vec{n}-\frac{\vec{a}}{2})(\Omega+L_{ij})(\vec{n}-\frac{\vec{a}}{2})+2^{t}(\vec{n}-\frac{\vec{a}}{2})(\vec{\theta}-\frac{\vec{b}}{2})\right)} \qquad (5.0.28) \\ &= \sum_{\vec{k}\in\mathcal{D}} e^{i\pi\left({}^{t}(\vec{n}-\frac{\vec{a}}{2})\Omega(\vec{n}-\frac{\vec{a}}{2})+2^{t}(\vec{n}-\frac{\vec{a}}{2})(\vec{\theta}-\frac{\vec{b}}{2})+{}^{t}(\vec{n}-\frac{\vec{a}}{2})L_{ij}(\vec{n}-\frac{\vec{a}}{2})\right)} \\ &= i^{a_i a_j} \sum_{\vec{k}\in\mathcal{D}} e^{i\pi\left({}^{t}(\vec{n}-\frac{\vec{a}}{2})\Omega(\vec{n}-\frac{\vec{a}}{2})+2^{t}(\vec{n}-\frac{\vec{a}}{2})(\vec{\theta}-\frac{\vec{b}}{2})-(a_i n_j + a_j n_i)\right)} \end{aligned}$$

since:

$$ {}^{t}(\vec{n} - \frac{\vec{a}}{2})L_{ij}(\vec{n} - \frac{\vec{a}}{2}) = 2(n_i - \frac{a_i}{2})(n_j - \frac{a_j}{2}) = 2n_i n_j - (a_i n_j + a_j n_i) + \frac{a_i a_j}{2} \qquad (5.0.29)$$

We set $\vec{b'} \equiv \vec{b} + a_i\vec{e_j} + a_j\vec{e_i} \mod (1,1)$ and obtain:

$$\begin{aligned} {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega + L_{ij}, \vec{\theta}) &= (-i)^{a_i a_j} \sum_{\vec{k}\in\mathcal{D}} e^{i\pi\left({}^{t}(\vec{n}-\frac{\vec{a}}{2})\Omega(\vec{n}-\frac{\vec{a}}{2})+2^{t}(\vec{n}-\frac{\vec{a}}{2})(\vec{\theta}-\frac{\vec{b'}}{2})\right)} \\ &= (-i)^{a_i a_j}\, {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b'}]}(\Omega, \vec{\theta}) \qquad (5.0.30) \end{aligned}$$

Now let $L_i \in M_d(\{0,1\})_{sym}$ and $(L_i)_{k,k'} = 0$ except for $k = i$, $k' = 1$. Then:

$$ {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega + L_i, \vec{\theta}) = (-1)^{(1-a_i)n_i}(\sqrt{i})^{a_i} \sum_{\vec{k}\in\mathcal{D}} e^{i\pi\left({}^{t}(\vec{n}-\frac{\vec{a}}{2})(\Omega)(\vec{n}-\frac{\vec{a}}{2})+2^{t}(\vec{n}-\frac{\vec{a}}{2})(\vec{\theta}-\frac{\vec{b}}{2})\right)} \qquad (5.0.31)$$

but with $\vec{b'} = \vec{b} + (1 - a_i)\vec{e_j}$, we have the result

$$ {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega + L_i, \vec{\theta}) = (\sqrt{i})^{a_i}\, {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b'}]}(\Omega, \vec{\theta}), \qquad (5.0.32)$$

and may state the theorem:

Theorem 5.1 *With the convention* $\sqrt{-1} = i$ *and* $\forall\Omega \in M_d^*([0,1[)_{inv}$ *and* $\forall\vec{\theta} \in]0,1[^d$*, the Gaussian sum in d dimensions admits the duality formula:*

- $$ {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega,\vec{\theta}) = \frac{(\sqrt{i})^{d}}{\det\Omega} e^{-i\pi {}^{t}\vec{\theta}\Omega^{-1}\vec{\theta}} \sum_{0\leq i_1,\ldots,i_d\leq d} \mathcal{O}(1)^{i_1+\ldots+i_d\,d}\sigma_{\mathcal{P}_1^{i_1}\ldots\mathcal{P}_d^{i_d}\Omega\mathcal{D}}^{[\vec{a},\vec{b}]}(-\Omega^{-1},\Omega^{-1}\vec{\theta}) \tag{5.0.33} $$

  We use also the convention $\mathcal{P}^0 = \mathbb{I}d$*, the identity map.*

- *For* $L_{ij} \in M_d(\{0,1\})_{sym}$ *introduced before and* $\vec{b'} \equiv \vec{b} + a_i\vec{e_j} + a_j\vec{e_i}$ mod $(1,1)$ *we also have:*

  $$ {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega + L_{ij},\vec{\theta}) = (-i)^{a_i a_j}\, {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b'}]}(\Omega,\vec{\theta}) \tag{5.0.34} $$

- *And for* $L_i \in M_d(\{0,1\})_{sym}$ *introduced before and* $\vec{b'} = \vec{b} + (1-a_i)\vec{e_j}$*, we obtain:*

  $$ {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega + L_i,\vec{\theta}) = (\sqrt{i})^{a_i}\, {}^{d}\sigma_{\mathcal{D}}^{[\vec{a},\vec{b'}]}(\Omega,\vec{\theta}) \tag{5.0.35} $$

The functions ${}^{d}C_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega,\vec{\theta})$ *and* ${}^{d}S_{\mathcal{D}}^{[\vec{a},\vec{b}]}(\Omega,\vec{\theta})$ *verify similar duality relations.*

If Ω is not invertible, one may perform a partial duality transformation. Up to a permutation of indices, the duality transformation may be applied to those of the indices for which the minors are non-zero and the number of indices corresponds simply to the rank of the matrix Ω. For the remaining indices the summation can be performed, since they are geometrical sums.

6 Applications to the computation of $\xi_n[\beta, x; P_i]$

Now back to Eq. 3.0.7 which we shall write using the notation of the previous section. The matrix Ω belongs to $M^*_{2q-1}(\mathbb{R})_{sym}$ and has the form

$$ \Omega = \frac{\beta}{\sum P_i} \begin{bmatrix} P_2(\sum P_i - P_2) & -P_2P_3 & \ldots & -P_2P_{2q} \\ -P_2P_3 & P_3(\sum P_i - P_3) & \vdots & -P_3P_{2q} \\ \vdots & \vdots & \ddots & \vdots \\ -P_2P_{2q} & -P_3P_{2q} & \ldots & P_{2q}(\sum P_i - P_{2q}) \end{bmatrix} \tag{6.0.1} $$

we note $\sum$ for $\sum_{i=2}^{2q}$ and

$$\vec{\theta} = x \begin{bmatrix} P_2 \\ P_3 \\ \vdots \\ P_{2q} \end{bmatrix} \in Vect_{2q-1}(\mathrm{I\!R}) \tag{6.0.2}$$

It is easy to see that $\det \Omega = 0$ $(\mathrm{rank}(\Omega) \leq 2(q-1))$. By just adding all the lines, we get a line of 0. Let us compute the minor:

$$\begin{aligned} &\det \frac{\beta}{\sum P_i} \begin{bmatrix} P_2(\sum P_i - P_2) & -P_2P_3 & \dots & -P_2P_{2q-1} \\ -P_2P_3 & P_3(\sum P_i - P_3) & \vdots & -P_3P_{2q-1} \\ \vdots & \vdots & \ddots & \vdots \\ -P_2P_{2q-1} & -P_3P_{2q-1} & \dots & P_{2q-1}(\sum P_i - P_{2q-1}) \end{bmatrix} \\ &= \beta^{2(q-1)} \frac{P_2 \dots P_{2q-1}}{(\sum P_i)^{2(q-1)}} \det \begin{bmatrix} \sum P_i - P_2 & -P_2 & \dots & -P_2 \\ -P_3 & \sum P_i - P_3 & \vdots & -P_3 \\ \vdots & \vdots & \ddots & \vdots \\ -P_{2q-1} & -P_{2q-1} & \dots & \sum P_i - P_{2q-1} \end{bmatrix} \end{aligned} \tag{6.0.3}$$

Now replacing the 1st line by the sum of all the lines, we obtain:

$$= \frac{\beta^{2(q-1)} P_2 \dots P_{2q}}{(\sum P_i)^{2(q-1)}} \det \begin{bmatrix} 1 & 1 & \dots & 1 \\ -P_3 & \sum P_i - P_3 & \vdots & -P_3 \\ \vdots & \vdots & \ddots & \vdots \\ -P_{2q-1} & -P_{2q-1} & \dots & \sum P_i - P_{2q-1} \end{bmatrix} \tag{6.0.4}$$

Replacing the j^{th} column by the difference of the j^{th} and first column. Doing it for all $j \geq 2$, we are led to the expression:

$$\begin{aligned} &= \beta^{2(q-1)} \frac{P_2 \dots P_{2q}}{(\sum P_i)^{2(q-1)}} \det \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ -P_3 & \sum P_i & 0 & \vdots & 0 \\ -P_4 & 0 & \sum P_i & \vdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -P_{2q-1} & 0 & 0 & \dots & \sum P_i \end{bmatrix} \\ &= \beta^{2(q-1)} \frac{P_2 \dots P_{2q}}{(\sum P_i)} \neq 0 \end{aligned} \tag{6.0.5}$$

Consequently we have the lemma

Lemma 10

$$rank(\Omega) = 2(q-1) \tag{6.0.6}$$

This result implies the duality transformation of ξ_n only with respect to indices $k_2, \ldots, k_{2q-1}$. Thus we have:

$$\Phi_{2(q-1)} = \left(\frac{i}{\beta}\right)^{(q-1)} \sqrt{\frac{\sum P_i}{P_2 \ldots P_{2q}}} e^{-i\pi^t(\theta_2,\ldots,\theta_{2q-1})\Omega^{-1}_{2(q-1)}(\theta_2,\ldots,\theta_{2q-1})} \tag{6.0.7}$$

with

$$\Omega|_{i,j=2,\ldots,2q-1} \overset{def}{=} \bar{\Omega} = \frac{1}{\sum P_i} \begin{bmatrix} P_2(\sum P_i - P_2) & \ldots & -P_2 P_{2q-1} \\ \vdots & \ddots & \vdots \\ -P_2 P_{2q-1} & \ldots & P_{2q-1}(\sum P_i - P_{2q-1}) \end{bmatrix} \tag{6.0.8}$$

Using the results of the above section we also obtain $\forall i = 2, \ldots, 2q-1$

$$\omega_{2q-1}|_{i,2q} = \frac{1}{(\sum P_i)^{2q-3} P_2 \ldots P_{2q}} \tag{6.0.9}$$

$$\det \begin{bmatrix} P_2(\sum P_i - P_2) & \ldots & -P_2 P_{2q} & \ldots & -P_2 P_{2q-1} \\ -P_2 P_3 & \ldots & -P_3 P_{2q} & \ldots & -P_2 P_{2q-1} \\ \vdots & \ddots & \vdots & & \vdots \\ -P_2 P_i & \ldots & -P_{2q} P_i & \ldots & -P_i P_{2q-1} \\ \vdots & & \vdots & \ddots & \vdots \\ -P_2 P_{2q-1} & \ldots & -P_{2q-1} P_{2q} & \ldots & -P_{2q-1}(\sum P_i - P_{2q-1}) \end{bmatrix}$$

In the last matrix we substitute the i$^{\text{th}}$ column by the sum of all the columns of the matrix such that i$^{\text{th}}$ column becomes:

$$[-P_i P_2, \ldots, P_i(P_1 + \ldots + \hat{P}_i + \ldots P_{2q}), \ldots, -P_i P_{2q-1}] \tag{6.0.10}$$

Such that $\omega_{2q-1}|_{i,2q} = 1$.We also have:

$$\begin{aligned} \begin{bmatrix} \theta_2^{2q-1} \\ \vdots \\ \theta_{2q-1}^{2q-1} \end{bmatrix} &= \bar{\Omega}^{-1} \begin{bmatrix} \theta_2 \\ \vdots \\ \theta_{2q-1} \end{bmatrix} \\ \theta_{2q-1}^{2q} &= \theta_{2q} + \ldots + \theta_2 \end{aligned} \tag{6.0.11}$$

At the end we get the form of Ω_{2q-2}:

$$\Omega_{2q-2} = \left[\begin{array}{cc} \begin{pmatrix} & & \\ & \bar{\Omega}^{-1} & \\ & & \end{pmatrix} & \begin{array}{c} 1 \\ \vdots \\ 1 \end{array} \\ \begin{array}{ccc} 1 & \dots & 1 \end{array} & 0 \end{array} \right] \tag{6.0.12}$$

where $\bar{\Omega}$ is the $(2q-2) \times (2q-2)$ matrix defined above. So considering all the results modulo 1, the matrix Ω_{2q-2} does not admit coupling between k_{2q} and k_i for $i = 2, \dots, 2q-1$. Consequently with

$$A_{\vec{n}} = A_{\underbrace{n-1, \dots, n-1}_{2q-2\,times}}$$

and $\theta_i = xP_i$, $\forall i = 2, \dots, 2q-1$

$$\mathcal{D}_{2q-1} \circ \dots \circ \mathcal{D}_2 \left(\xi_n(\beta, x; P_2, \dots, P_{2q}) \right) = \left(\frac{i}{\beta} \right)^{q-1} \sqrt{\frac{\sum_{i=1}^{2q} P_i}{P_2 \dots P_{2q}}} \tag{6.0.13}$$

$$e^{-i\pi^t(\theta_2,\dots,\theta_{2q-1})\bar{\Omega}^{-1}(\theta_2,\dots,\theta_{2q-1})} \sum_{k_1=0}^{n-1} \sum_{k_{2q}=0}^{n-1} e^{2\pi x(k_{2q}-k_1)\sum P_i} \sum_{2 \leq i_2,\dots,i_{2q-1} \leq 2q-1}$$

$$\mathcal{O}(1)^{i_2+\dots+i_{2q-1}} . ^{2q-2} \sigma^{[\vec{0},\vec{0}]}_{\mathcal{P}_{i_2} \circ \dots \circ \mathcal{P}_{i_{2q-1}[\bar{\Omega} A_{\vec{n}}]}} \left(-\frac{\bar{\Omega}^{-1}}{\beta}, \frac{\bar{\Omega}^{-1}}{\beta} \vec{\bar{\theta}} \right)$$

where $\vec{\bar{\theta}}$ stands for the vector:

$$\vec{\bar{\theta}} = \begin{bmatrix} \theta_2 \\ \vdots \\ \theta_{2q-1} \end{bmatrix} \tag{6.0.14}$$

Hence:

$$\xi_n(\beta, x; P_2, \dots, P_{2q}) = \mathcal{O}(1) \sqrt{\frac{\sum_{i=1}^{2q} P_i}{P_2 \dots P_{2q}}} \sum_{k_1}^{n-1} \sum_{k_{2q}}^{n-1} e^{2\pi x(k_{2q}-k_1)\sum P_i}$$

$$\sum_{2 \leq i_2,\dots,i_{2q-1} \leq 2q-1} \sigma^{[\vec{0},\vec{0}]}_{\mathcal{P}_{i_2} \circ \dots \circ \mathcal{P}_{i_{2q-1}[\bar{\Omega} A_{\vec{n}}]}} \left(-\bar{\Omega}^{-1}, \bar{\Omega}^{-1} \vec{\bar{\theta}} \right) \tag{6.0.15}$$

Here we are reduced to compute the σ-functions, with Ω a matrix with integer entries of the form:

$$\sigma^{[\vec{0},\vec{0}]}_{A_{\vec{n}}}\left(\lambda\Omega,\vec{\theta}\right) = \sum_{\vec{k}\in A_{\vec{n}}} e^{i\pi(\lambda^t\vec{k}\Omega\vec{k}+{}^t\vec{k}\vec{\theta})} \tag{6.0.16}$$

where $\lambda \in \mathbb{R}$

Lemma 11 *For any matrix Ω with integer entries, there exists a basis $(\vec{k}')$ such that the quadratic form ${}^t\vec{k}\Omega\vec{k}$ becomes:*

$${}^t\vec{k}\Omega\vec{k} = \lambda_1 {k'_1}^2 + \ldots + \lambda_{2q-2}{k'_{2q-2}}^2 = {}^t\vec{k}'\Lambda\vec{k}' \tag{6.0.17}$$

where Λ is a diagonal matrix with rational entries. If we note $\vec{k}' = U\vec{k}$, U has also integer entries.

Proof. Let us write down explicitly the expression of the quadratic form:

$$\begin{aligned}
\sum_{ij}\omega_{i,j}k_ik_j &= \sum_{1\leq i\leq d}\omega_{ii}k_i^2 + 2\sum_{1\leq i<j\leq d}\omega_{ij}k_ik_j \\
&= \omega_{mm}\left(k_m + \sum_{i=1,\, i\neq m}^{d}\frac{\omega_{mi}}{\omega_{mm}}k_i\right)^2 - \omega_{mm}\left(\sum_{i=1,\, i\neq m}^{d}\frac{\omega_{mi}}{\omega_{mm}}k_i\right)^2 \\
&+ 2\sum_{1\leq i<j\leq d,\, (i,j)\neq m}\omega_{ij}k_ik_j \\
&= \omega_m {k'}^2_m + \sum_{i=1,\, i\neq m}\omega'_{ii}{k'}^2_i + 2\sum_{1\leq i<j\leq d,\, (i,j)\neq m}\omega'_{ij}{k'}_i{k'}_j
\end{aligned} \tag{6.0.18}$$

So by redefining the ω'_{ij} and proceeding by induction we obtained the expected result. ■

The transition matrix U used for the change of basis can be taken with integer entries instead of rational entries. Thus $\forall i = 1,\ldots,d$, $k'_i = \sum_{j=1}^{d} B_{ij}k_j$ and U is of course invertible. Moreover, up to a permutation of indices one can insure that the next minor is non-zero. We set then

$$U' = \begin{bmatrix} U_{11} & \ldots & U_{1,d-1} \\ \vdots & & \vdots \\ U_{d-1,1} & \ldots & U_{d-1,d-1} \end{bmatrix} \tag{6.0.19}$$

and $\det(U') \neq 0$. Let $\mathcal{D}$ be a bounded domain of $\mathbb{N}^d$ and let $\vec{P} \in U(\mathcal{D})$. Then $\vec{P}$, by construction, is a vector with integer components and $\exists \vec{k} \in \mathcal{D}$ such that $\vec{P} = U\vec{k}$. At this stage, one should show that $U(\mathcal{D})$ can be decomposed into integer sub-lattices R_i of lattice spacing $\delta_i \in \mathbb{N}$. Thus $\vec{P} \in R_i$, then $\vec{P} + \delta_i \vec{e}_j \in R_i$ with $\vec{e}_j$, $j = 1, \ldots, d$ is a unit vector. R_i is defined inside the boundary of $U(\mathcal{D})$. To prove this last property one must solve in $\mathbb{N}^d$, the system $\forall i = 1, \ldots, d-1$:

$$\begin{aligned} \sum_{j=1}^{d} B_{ij} k_j &= 0 \\ \sum_{j=1}^{d} B_{dj} k_j &= \delta \end{aligned} \tag{6.0.20}$$

We have thus

$$U' = \begin{bmatrix} k_1 \\ \vdots \\ k_{d-1} \end{bmatrix} = -k_d \begin{bmatrix} U_{1,d} \\ \vdots \\ U_{1,d-1} \end{bmatrix} \tag{6.0.21}$$

and as $\det U' \neq 0$ then:

$$\begin{bmatrix} k_1 \\ \vdots \\ k_{d-1} \end{bmatrix} = -\frac{k_d}{\det U'} \tilde{U}' \begin{bmatrix} U_{1,d} \\ \vdots \\ U_{1,d-1} \end{bmatrix} \tag{6.0.22}$$

where $\tilde{U}'$ is a matrix of cofactor of U' (with integer entries). Let us take $k_d = -\det U'$ so we have determined in $\mathbb{N}^d$ the solution the above equations :

$$\begin{bmatrix} k_1 \\ \vdots \\ k_{d-1} \end{bmatrix} = \tilde{U}' \begin{bmatrix} U_{1,d} \\ \vdots \\ U_{1,d-1} \end{bmatrix} \tag{6.0.23}$$

It is clear that any multiple of this vector is a solution. Let us compute now δ, defined by:

$$\delta = \sum_{j=1}^{d} U_{dj} k_j = U_{dd} \det U' + \sum_{i=1}^{d-1} \sum_{j=1}^{d-1} U_{dj} \tilde{U}'_{ij} U_{id} \tag{6.0.24}$$

Thus $\delta = \det U$ by expanding with respect to the last line and column, we obtain:

Proposition 12 *Let $U(\mathcal{D})$ be a bounded domain of $I\!N^d$ and U an integer invertible matrix . Then there exists at most δ^d hypercubess $R_i \in I\!N^d$ of lattice spacing δ_i (δ_i being a divisor of δ, with $\delta = \det U$), such that $\forall P \in U(\mathcal{D})$, $\exists 1 \leq i \leq \delta^d$ for which $P \in R_i$. The hypercubes $(R_i)_{i=1,\ldots,\delta^d}$ are all limited by boundaries of $U(\mathcal{D})$.*

Proposition 13 *Let $(\mathcal{F}_n)_{n\in I\!N}$ be a family of hypercubes of $I\!N^d$, defined by $\vec{k} = (k_1, \ldots, k_d) \in \mathcal{F}_n$ with $\forall 1 \leq i \leq d$, $k_i \in I\!N$ and $1 \leq k_i \leq n$. Let $(\mathcal{D}_n)_{n\in I\!N}$ be an increasing sequence of connected domains of $I\!N^d$ such that there exists $t \in I\!R$ for which $\forall n \in I\!N$: $\mathcal{F}_n \subset \mathcal{D}_n \subset \mathcal{F}_{tn}$. Then, uniformly with respect to θ:*

$$ {}^d\sigma_{\mathcal{D}_n}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) \underset{n\to\infty}{\sim} {}^d\sigma_{\mathcal{F}_n}^{[\vec{0},\vec{0}]}(\Omega, \vec{\theta}) \tag{6.0.25} $$

Proof.

$\mathbb{N}^d$ as a partially ordered set, we can easily prove that $\forall(\vec{a}, \vec{b}) \in Vect_d(\{0, 1\})$, $\forall\Omega \in M_d(\mathbb{R})$ and $\forall\vec{\theta} \in Vect_d(\mathbb{R})$ the mapping ${}^d\sigma_{(.)}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta})$ defined as follows is increasing:

$$ \begin{array}{rccc} {}^d\sigma_{(.)}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) : & \mathcal{P}(\mathbb{N}^d) & \longrightarrow & \mathbb{C} \\ & \mathcal{F} & \longmapsto & {}^d\sigma_{\mathcal{F}}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) \end{array} \tag{6.0.26} $$

So for n sufficiently large we have: ${}^d\sigma_{\mathcal{F}_n}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) \leq {}^d\sigma_{\mathcal{D}_n}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) \leq {}^d\sigma_{\mathcal{F}_{tn}}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta})$. Now taking in account that: ${}^d\sigma_{\mathcal{F}_{tn}}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) = \mathcal{O}({}^d\sigma_{\mathcal{F}_n}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}))$, we can conclude that ${}^d\sigma_{\mathcal{D}_n}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}) = \mathcal{O}({}^d\sigma_{\mathcal{F}_n}^{[\vec{a},\vec{b}]}(\Omega, \vec{\theta}))$ and is homogeneous in $\vec{\theta}$. ■

Remark 14

Here we just recall the result of [DM] that: $\forall\chi \in [1/2, 1]$ $\exists x \in \mathbb{R}$ such that ${}^1\sigma_n^{[0,0]}(x, 0) = \mathcal{O}(n^\chi)$.

According to [HL pp. 202], the hypothesis of uniformity is automatically verified in Gaussian sums with $d = 1$. This hypothesis remains valid for

d-dimensional Gaussian sums. Let $R_1(\vec{n}), \ldots, R_d(\vec{n})$ the sub-lattices making up $B(\tilde{\Omega} A_{\vec{n}})$. Then we have:

$$\begin{aligned}&\sum_{0 \leq i_2, \ldots, i_{2q-2} \leq 2q-1} \mathcal{O}(1)^{i_2 + \ldots + i_{2q-1}} . {}^{2q-2}\sigma^{[\vec{0},\vec{0}]}_{\mathcal{P}_{i_2} \circ \ldots \circ \mathcal{P}_{i_{2q-1}}(\tilde{\Omega} A_{\vec{n}})}(-\frac{\bar{\Omega}^{-1}}{\beta}, \frac{\bar{\Omega}^{-1}}{\beta}\vec{\bar{\theta}}) \\ &= \sum_{j=1}^{s} \sum_{\substack{i_2 \in [1,2q-1], \ldots, \\ i_{2q-2} \in [1,2q-1]}} \mathcal{O}(1)^{i_2 + \ldots + i_{2q-1}} . {}^{2q-2}\sigma^{[\vec{0},\vec{0}]}_{\mathcal{P}_{i_2} \circ \ldots \circ \mathcal{P}_{i_{2q-1}}(R_j)}(-\frac{\Lambda}{\beta}^{-1}, -\frac{\Lambda}{\beta}^{-1}\vec{\bar{\theta}}')\end{aligned} \tag{6.0.27}$$

with $\vec{\bar{\theta}}' = B^{-1}\vec{\bar{\theta}}$, where B is the matrix of basis change described in lemma 11 such that Λ is a diagonal matrix with integer (or rational) entries. Since Λ has integer matrix elements, it follows from the above formula that there exists a finite number of sub-lattices for which the multi-variable sum is reduced to a product of $(2q-2)$ factors of one-dimensional Gaussian sums where each factor is of the form ${}^{1}\sigma^{[\vec{0},\vec{0}]}_{(R_j)}(-\frac{1}{\lambda\beta}, -\frac{1}{\lambda\beta}\theta)$ where λ is an eigenvalue of Λ. The following section will consider the problem of the asymtotic behavior of such Gaussian sums.

6.1 Estimations of Gaussian sums using the duality formula

We shall now present the theorem which motivates the previous construction. Let us recall the method of Hardy et Littelwood using the duality formula for the computation of the Gaussian sums. They give the expression, $\forall x \in]0,1[$, $\forall \theta \in]0,1[$ and $\forall (a,b) \in \{0,1\}$, and any $n \in \mathbb{N}$:

$${}^{1}\sigma^{[a,b]}_{n}(x, \theta) = \mathcal{O}(1)\sqrt{n x x_1 \ldots x_\nu} + \frac{\mathcal{O}(1)}{\sqrt{x x_1 \ldots x_\nu}} \tag{6.1.1}$$

Recall briefly the steps: For convenience let us denote $x_0 = x$. $\forall i = 0, \ldots, \nu$, we have $0 < x_i < 1$. x_i are the rest of the development in continuous fractions of x:

$$x = \frac{1}{a_1 + \frac{1}{a_2 + \ldots}} \overset{not.}{=} [a_1, a_2, \ldots,] \tag{6.1.2}$$

and $\forall i > 0$ the $(x_i)_{i\in\mathbb{N}}$ are given inductively by the relation:

$$x_{i-1} = \frac{1}{a_i + x_i} \tag{6.1.3}$$

Hence, for any n, there is an integer ν determined in such a way that :

$$nx_0 \dots x_\nu \leq 1 \leq nx_0 \dots x_{\nu-1} \tag{6.1.4}$$

Through this condition, the first term on the r.h.s. in Eq.6.1.1 becomes irrelevant with respect to the second one. Let us put $\nu = \nu(n)$ in the above expression. So there exists a positive constant H such that:

$$x_0 \dots x_\nu \geq H a_{\nu(n)}^{-1} x_0 \dots x_{\nu-1} \tag{6.1.5}$$

Hence we obtain by using Eq.6.1.4 and Eq.6.1.5:

$$\frac{1}{\sqrt{x_0 \dots x_\nu}} = \mathcal{O}(\sqrt{a_{\nu(n)} n}) \tag{6.1.6}$$

If we use the trivial estimation ($x_i x_{i+1} < \frac{1}{2}$) we deduce that necessarily $\forall \epsilon > 0$:

$$\nu(n) < \frac{2+\epsilon}{\ln 2} \ln n \tag{6.1.7}$$

thus:

- if $a_n = \mathcal{O}(1)$ then ${}^1\sigma_n^{[a,b]}(x,\theta) = \mathcal{O}(\sqrt{n})$
- if $a_n = \mathcal{O}(n^\rho)$ then ${}^1\sigma_n^{[a,b]}(x,\theta) = \mathcal{O}(\sqrt{n}(\ln n)^{\frac{\rho}{2}})$
- if $a_n = \mathcal{O}(e^{n\rho})$, with $0 < \rho < \frac{\ln 2}{2}$ then ${}^1\sigma_n^{[a,b]}(x,\theta) = \mathcal{O}(\sqrt{n} n^{\frac{\rho}{\ln 2}+\epsilon})$

Nevertheless let us recall that the equidistribution of $e^{i\pi x k^2}$, for any irrational x, [K] and [KN] give the upper bound of:

$${}^1\sigma_n^{[a,b]}(x,\theta) = o(n) \tag{6.1.8}$$

Now we must use other results of number theory concerning the computation of continuous fraction expansion of a fraction of the numbers occurring as arguments in our Gaussian sums ${}^1\sigma_{(R_j)}^{[\vec{0},\vec{0}]}(-\frac{1}{\lambda\beta}, -\frac{1}{\lambda\beta}\theta)$, of the form:

$${}^1\sigma_n^{[a,b]}\left(\frac{ux+v}{tx+w}, \theta\right) \leq K.\left({}^1\sigma_n^{[0,0]}(x,0)\right) \tag{6.1.9}$$

where $(u, v, t, w) \in \mathbb{N}^4$.

We will refer to the article of Raney [R] and to the survey of Van der Poorten [VdP]. Let us introduce some notations:

$$\begin{array}{rccc} \Psi_k : &]0,1[& \longrightarrow & {\mathbb{N}^*}^{\mathbb{N}} \\ & x & \longmapsto & [a_1, a_2, \ldots, a_k] \end{array} \tag{6.1.10}$$

such that

$$\Psi_k(x) = \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{\ldots + \frac{1}{a_k}}}} \tag{6.1.11}$$

Denote Ψ_∞ the map which associates to any real number its continuous fraction. Ψ_∞ is a homeomorphism from $]0,1[$ to ${\mathbb{N}^*}^{\mathbb{N}}$. Referring to the theorem of convergence for continuous fraction, for any $x \in]0,1[$ we have:

$$\Psi_\infty^{-1} \circ \Psi_k(x) \underset{k\to\infty}{\longrightarrow} x \tag{6.1.12}$$

Consider now the matrix representation $\{R, L\}$ of the expansion in continuous fractions of x:

$$R = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \qquad L = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \tag{6.1.13}$$

Here $\forall k \in \mathbb{N}^*$ one gets

$$R^k = \begin{bmatrix} 1 & k \\ 0 & 1 \end{bmatrix} \qquad L^k = \begin{bmatrix} 1 & 0 \\ k & 1 \end{bmatrix} \tag{6.1.14}$$

So $\Psi_k^{-1}([a_1, \ldots, a_k]) \in \mathbb{Q}$ is determined by the formula:

$$\Psi_k^{-1}([a_1, \ldots, a_k]) = \frac{\sum_{i=1}^{2} (R^{a_1} L^{a_2} \ldots R^{a_k})_{1,i}}{\sum_{i=1}^{2} (R^{a_1} L^{a_2} \ldots R^{a_k})_{2,i}} \tag{6.1.15}$$

Now we use the main result of the articles quoted above:

The continuous fraction of $\frac{ax+b}{cx+d}$ is related to that of x if $ad - ac \neq 0$. To this end, let us consider the set of 2×2 matrices of positive integer entries:

$$\mathcal{E}_n = \left\{ M = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M_2(\mathbb{N}) | \quad n = \det M \neq 0, a > c, b < d \right\} \tag{6.1.16}$$

The number of such matrices is finite [R]. Denote by $\mathcal{E}_n = \{A_1, \ldots, A_N\}$. The commutation relations obey some restrictions: $\forall i = 1, \ldots, N$, $\exists i^{'}, i^{"} = 1, \ldots, N$ such that:

$$\begin{aligned} A_i R^{k^1_R} L^{k^1_L} &= L^{k'^1_L} R^{k'^1_R} A_{i'} \\ A_i L^{k^2_L} R^{k^2_R} &= R^{k'^2_R} L^{k'^2_L} A_{i''} \end{aligned} \tag{6.1.17}$$

with (k^1_R, k^1_L) positive exponents such that $1 \leq k^1_R + k^1_L \leq n$ and so on. The algorithm which allows to compute, for a given n, the matrices in the left hand side is given below. We note that these commutation relations are invariant under transposition:

$$\begin{aligned} A_i R^{k^1_R} L^{k^1_L} &= L^{k^{1'}_L} R^{k^{1'}_R} A_{i'} \\ {}^tA_{i'} R^{k^{1'}_R} L^{k^{1'}_L} &= L^{k^1_L} R^{k^1_R}\, {}^tA_i \end{aligned} \tag{6.1.18}$$

Note that for any $n \in \mathbb{N}^*$

$$\begin{aligned} \begin{pmatrix} n & 0 \\ 0 & 1 \end{pmatrix} R &= R^n \begin{pmatrix} n & 0 \\ 0 & 1 \end{pmatrix} \\ \begin{pmatrix} n & 0 \\ 0 & 1 \end{pmatrix} L &= L^n \begin{pmatrix} n & 0 \\ 0 & 1 \end{pmatrix} \end{aligned} \tag{6.1.19}$$

This provides an algorithm to compute the expansion into continued fraction of the values of the function $x \mapsto \frac{ax+b}{cx+d}$

6.2 Illustration of the algorithm

We now shall illustrate this method for $n = 2$. The set $\mathcal{E}_2$ is made up two matrices which represent the multiplication and the division by 2:

$$\mathcal{E}_2 = \{A, A'\} \tag{6.2.1}$$

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix} \qquad A' = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix} \tag{6.2.2}$$

The rules of commutation are compiled in the following tabulation:

	A	A'
A	$R : R^2$ $L^2 : L$	$LR : RL$
A'	$RL : LR$	$R^2 : R$ $L : L^2$

(6.2.3)

The table is to be red following the exemple of the first entry:$AR = R^2A$. These relations are equivalent to the following distinct cases:

$$\begin{array}{rcr} x=[0,2a,b,\ldots] & \Rightarrow & 2x=[0,a,2b,\ldots] \\ x=[0,2a+1,b,\ldots] & \Rightarrow & 2x=[0,a,1,1,(b-1)/2,\ldots] \end{array} \tag{6.2.4}$$

The entire determination of $2x$ from x is done by induction with respect to those rules. For example, if $x = [7, 2, 5, \ldots]$ then

$$2x = [3, 1, 1, 0, 1, 1, 2, \ldots] = [3, 1, 2, 1, 2, \ldots] \tag{6.2.5}$$

Let us introduce some notations: $[x_0, x_1, \ldots]$ with $0 < x_i < 1, \forall i \in \mathbb{N}$, the sequence of the rest deduced by the decomposition into continuous fractions of $x = x_0$. We shall denote the resulting sequence of the rest of $2x$ by $2x = x'_0 = [x'_0, x'_1, \ldots]$. Thus we have , by definition, the relation:

$$x_i = -b_{i+1} + \frac{1}{x_{i+1}} \tag{6.2.6}$$

where $x = [0; b_1, b_2, \ldots]$. As the formula Eq 6.2.4 shows, the processus of commutation (resulting of the multiplication by 2 generates a lag length between the two sequences ($x = [0; b_1, b_2, \ldots]$ and $2x = [0; b'_1, b'_2, \ldots]$). We shall define a function (depending on the decomposition of x) which measures the length of $2x$ with respect to x.

$$\begin{array}{rccc} k'_x : & \mathbb{N} & \longrightarrow & \mathbb{N} \\ & k & \longmapsto & k'_x(k) \end{array} \tag{6.2.7}$$

such that :

- if 2 divides b_1 (in what follows denoted as: $2 \mid b_1$), then $k'_x(k_1) = k_1$ and $k'_x(k_2) = k_2$
- if 2 does not divide b_1 (in what follows denoted as $2 \nmid b_1$) then $k'_x(k_1) = k_1 + 3$ and
  - if $2 \nmid b_2$ then $k'_x(k_2) = k'_x(k_1) + 1$
  - if $2 \mid b_2$ then $k'_x(k_2) = k'_x(k_1) + 3$

and so one... We recall the trivial reduction which occurs when one of the components of the decomposition is zero, we shall refer to the example Eq 6.2.5. Note for this x , $k'_x(3) = 5$.

Lemma 15 *$\forall p \in \mathbb{N}$, let $[x_0, x_1, \ldots]$, $[x'_0, x'_1, \ldots]$ be the rests of the expansion of x and $x' = px$ respectively, then $\forall k \in \mathbb{N}\, \exists C \in \mathbb{N}$ which divides k (possibly $C = 1$). such that*

$$x'_1 \ldots x'_{k'_x(k)} = Cx_1 \ldots x_k \tag{6.2.8}$$

where $[x_0, x_1, \ldots]$, $[x'_0, x'_1, \ldots]$ are respectively the rest sequence of x and px.

Proof.

We shall reduce the proof to the simplest case $p = 2$. The other case is quite the same but it turns out to be more difficult because of an involved algebra. We prove the lemma distinguishing all the possibilities:

- if $2 \mid b_1$ then $b'_1 = \frac{b_1}{2}$. Compute now $x'_0 x'_1 = x'_0 \left(-b'_1 + \frac{1}{x'_0}\right) = 1 - b_1 x_0 = x_0 x_1$. Consequently $x'_1 = \frac{x_1}{2}$. Since $2 \mid b_1$ then $b'_2 = 2b_2$ and $x'_1 x'_2 = 1 - b'_2 x'_1 = 1 - b_2 x_1 = x_1 x_2$ and $x'_2 = 2x_1$.

  At this level we have two possibilities either $2 \mid b_3$ and the procedure repeats itself identically or $2 \nmid b_3$, in this case we shall refer to the following

- if $2 \nmid b_1$ then $b'_1 \frac{b_1 - 1}{2}$ and $b'_2 = b'_3 = 1$. Hence let us calculate $x'_0 x'_1 x'_2 x'_3$: $x'_0 x'_1 x'_2 x'_3 = -(2b'_1 + 1)x'_0 + 2 = -2b_1 x_0 + 2 = 2(1 - b_1 x_0) = 2x_1 x_0$ so $x_1 = x'_1 x'_2 x'_3$. We establish another relation $x'_0 x'_1 x'_2 = (1 + b'_1)x'_0 + 1$ then $x'_1 x'_2 = 1 + b'_1 - \frac{1}{x'_0} = \frac{1 - x_1}{2}$ ie $x_1 + 2x'_1 x'_2 = 1$ and we deduce that $(1 - x_1)x'_3 = 2x_1$

- If $2 \nmid b_2$ then $b'_4 = \frac{b_2 - 1}{2}$ and $b'_5 = 2b_3$. Calculating $x'_3 x'_4 x'_5 = x'_3(1 + b'_5 b'_4) - b'_5$, so $x'_4 x'_5 = 1 + b_2 b_3 - \frac{b_3}{x_1} = x_2 x_3$. We also prove that $-b'_5 x'_4 + 1 = x_2 x_3 = -b_3 x_2 + 1$ so $x'_4 = \frac{x_2}{2}$ and $x'_5 = 2x_3$.

- If $2 \mid b_2$ then $b'_4 = \frac{b_2 - 2}{2}$ end $b'_5 = b'_6 = 1$. $x'_3 x'_4 x'_5 x'_6 = 2 - (b_2 - 1)x'_3$. So using $2x_1 = x'_3(1 - x_1)$ we get $x'_4 x'_5 x'_6 = x_2$. we also get $2x'_4 x'_5 + x_2 = 1$. So let us summarize these results in the following tables:

$x =$	$2b_1$	b_2	$2b_3$		
x_0	x_1	x_2	x_3		
$2x =$	b_1	$2b_2$	b_3		
$x'_0 = 2x_0$	$x'_1 = \frac{x_1}{2}$	$x'_2 = 2x_2$	$x'_3 = \frac{x_3}{2}$		

$x =$	$2b_1$	b_2	$2b_3 + 1$		
x_0	x_1	x_2	x_3		
$2x =$	b_1	$2b_2$	b_3	1	1
$x'_0 = 2x_0$	$x'_1 = \frac{x_1}{2}$	$x'_2 = 2x_2$	x'_3 $x_3 = x'_3x'_4x'_5$ $x'_3x'_4 + 2x_3 = 1$	x'_4	x'_5

(6.2.9)

and we also have:

$x =$	$2b_1 + 1$			$2b_2 + 1$	b_3	
x_0	x_1			x_2	x_3	
$2x =$	b_1	1	1	b_2	$2b_3$	
$x'_0 = 2x_0$	x'_1 $x_1 = x'_1x'_2x'_3$ $x'_1x'_2 + 2x_1 = 1$	x'_2	x'_3	$\frac{x_2}{2}$	$2x_3$	

$x =$	$2b_1 + 1$			$2b_2 + 2$		
x_0	x_1			x_2		
$2x =$	b_1	1	1	b_2	1	1
$x'_0 = 2x_0$	x'_1 $x_1 = x'_1x'_2x'_3$ $x'_1x'_2 + 2x_1 = 1$	x'_2	x'_3	x'_4 $x_2 = x'_4x'_5x'_6$ $x'_4x'_5 + 2x_2 = 1$	x'_5	x'_6

(6.2.10)

Thus we have : $\forall k \in \mathbb{N}\ x_1 \dots x_k = x'_1 \dots x'_{k'(k)}$ or $2x_1 \dots x_k = x'_1 \dots x'_{k'(k)}$. This complete the proof of the lemma. ■

More generically, let $A \in \mathcal{E}_n$ goes through the string $R^{a_1}L^{a_2}R^{a_3}\dots$, commuting with respect to the two matrices $\{R, L\}$: $[AR^{a_1}L^{a_2}R^{a_3}\dots R^{a_k}] \mapsto [R^{a'_1}L^{a'_2}R^{a'_3}\dots R^{a'_{k'}}A']$ with $A' \in \mathcal{E}_n$. This procedure gives an algorithm for the computation of:

$$\Psi_{k'(k)}\left(\frac{ax+b}{cx+d}\right) = [a'_1, a'_2, a'_3, \dots, a'_{k'(k)}] \tag{6.2.11}$$

which only depends on $[a_1, a_2, \ldots, a_k]$. Now using the above lemma in the formula Eq 6.1.1, we obtain the theorem:

Theorem 6.1 *$\forall (u, v, t, w) \in I\!N^4$, $\forall x \in I\!R \setminus \mathbb{Q}$, $\forall \theta \in [0, 1[$ and $\forall (a, b) \in \{0, 1\}$, then*

$$ {}^1\sigma_n^{[a,b]}\left(\frac{ux+v}{tx+w}, \theta\right) = \mathcal{O}\left({}^1\sigma_n^{[0,0]}(x, 0)\right) \tag{6.2.12}$$

By applying this theorem to the above expression one can deduce that:

$$\begin{aligned} \xi_n(x, \beta; P_2, \ldots, P_{2q}) &= \sqrt{\frac{\sum P_i}{P_2 \ldots P_{2q}}} \sum_{k_1=0}^{n-1} \sum_{k_{2q}=0}^{n-1} e^{2i\pi x(k_{2q}-k_1)(\sum P_i)} \\ &\times \mathcal{O}({}^1\sigma_n^{[a,b]}(\beta, 0))^{2q-2} \end{aligned} \tag{6.2.13}$$

Remark 16

The estimation depends on (u, v, t, w). It remains an essential question: does there exist a constant K independant of $(u, v, t, w) \in I\!N^4$ such that

$$ {}^1\sigma_n^{[a,b]}\left(\frac{ux+v}{tx+w}, \theta\right) \leq K. \left({}^1\sigma_n^{[0,0]}(x, 0)\right) \tag{6.2.14}$$

This result is not trivial to prove. In fact, if this assertion were true, the characteristic function would be analytical in a neighborhood of zero. Consequently, this work only gives a partial answer.

Remark 17

We observe that this result is an optimal estimation [HL p225, theorem 2.221] when applied to the matrix case: for any Λ is an integer invertible matrix, and for any $\beta \in I\!R \setminus \mathbb{Q}$, we have:

$$ {}^d\sigma_{A_{\vec{n}}}^{[\vec{a},\vec{b}]}(\beta\Lambda, \vec{\theta}) = \mathcal{O}({}^1\sigma_n^{[0,0]}(\beta, 0))^d \tag{6.2.15}$$

It cannot be replaced by a better estimate.

Now we can compute the mean value of $S_n^{2q}\left(\frac{\pi\beta}{4}\right)$ (see Eq. 3.0.5):

$$\begin{aligned} E\left[S_n^{2q}\left(\frac{\pi\beta}{4}\right)\right] &= (-1)^q\left(\frac{4}{\pi}\right)^q \sum_{P_i\in\tilde{\mathbb{Z}}} \frac{1}{\prod P_i(\sum P_i)} \int_0^1 \xi_n(x,\beta;P_2,\ldots,P_{2q})dx \\ &= (-1)^q\left(\frac{4}{\pi}\right)^q \sum_{P_i\in\tilde{\mathbb{Z}}} \frac{\mathcal{O}({}^1\sigma_n^{[0,0]}(\beta,0))^{2(q-1)}}{(\prod P_i)^{\frac{3}{2}}\sqrt{\sum P_i}} \sum_{k_1=0}^{n-1}\sum_{k_{2q}=0}^{n-1}\int_0^1 e^{2i\pi x(k_{2q}-k_1)\sum P_i}dx \end{aligned} \tag{6.2.16}$$

where $\prod$ stands for $\prod_{i=2}^{2q}$. Performing the integral in x yields the condition $k_1 = k_{2q}$, we end up with:

$$\begin{aligned} E\left[S_n^{2q}\left(\frac{\pi\beta}{4}\right)\right] &= n\sum_{P_i\in\tilde{\mathbb{Z}}} \frac{\mathcal{O}({}^1\sigma_n^{[0,0]}(\beta,0))^{2(q-1)}}{(\prod P_i)^{\frac{3}{2}}\sqrt{\sum P_i}} \\ &= n.c_q.\mathcal{O}({}^1\sigma_n^{[0,0]}(\beta,0))^{2(q-1)} \end{aligned} \tag{6.2.17}$$

$\mathcal{O}({}^1\sigma_n^{[0,0]}(x,0))^{2(q-1)}$ depends on n but also on $(P_2,\ldots,P_{2(q-1)})$. Moreover $c_q$is finite because the moments are perfectly defined (the integration is done over a compact set $[0,2\pi[\times[0,2\pi[$). So:

$$E\left[S_n^{2q}\left(\frac{\pi\beta}{4}\right)\right] = n.\mathcal{O}\left({}^1\sigma_n^{[0,0]}(\beta,0)^{2(q-1)}\right) \tag{6.2.18}$$

Remark 18

For $q=1$, we recover the exact result $E\left[S_n^{2q}\left(\frac{\pi\beta}{4}\right)\right] = n$, which is independent of the choice of β.

Theorem 6.2 *The unique sequence f_n (up to an equivalence as $n\to\infty$) in order that:*

$$E\left[\frac{S_n\left(\frac{\pi\beta}{4}\right)}{f_n}\right]^{2q} = \mathcal{O}(1) \tag{6.2.19}$$

with respect to n for all q, is $f_n = \sqrt{n}$. This estimate is true for all β such that ${}^1\sigma_n^{[0,0]}(\beta,0) = \mathcal{O}(\sqrt{n})$

Proof.

We must choose a β having a bounded continuous fractions representation to have f_n indenpendent of q. The proof results straightforwardly from the remark 14 that is:

$$\frac{f_n^2}{n^q}\left(\frac{{}^1\sigma_n^{[0,0]}\left(\frac{\pi\beta}{4},0\right)}{f_n}\right)^{2q} = \mathcal{O}(1) \tag{6.2.20}$$

■

Remark 19

Note that if $\beta \in \mathbb{Q}$ then [HL] ${}^1\sigma_n^{[0,0]}(\beta,0) = \mathcal{O}(n)$ and we recover the result established earlier, i.e:

$$E\left[S_n^{2q}\left(\frac{\pi\beta}{4}\right)\right] = \mathcal{O}(n^{2q-1}) \tag{6.2.21}$$

which means that there is no normalization of S_n for which the moments neither diverge nor be non-zero.

Examples of numbers β which admit an expansion as an infinite and bounded continued fractions are the quadratic irrationals. They have ultimately periodic continued fraction expansion. This class contains all the square roots of products of pairwise distinct prime integers, and of course we have, for those numbers, $\forall q \in \mathbb{N}$

$$E\left[S_n^{2q}\left(\frac{\pi\beta}{4}\right)\right] = \mathcal{O}(n^{q}) \tag{6.2.22}$$

Hence there exists here a normalization $\sqrt{n}$ of S_n for which all moments remain bounded with respect to n and are not zero.

Remark 6.3

Any attempt to obtain information to the convergence in distribution of S_n/f_n by using numerical computations cannot be correct since behaviors are radically different according to the nature of the number β and the rational numbers are dense in $\mathbb{R}$. Finally all of these calculations may be applied in the same way to any periodic function instead of the signum function $\chi(y)$.

As to the problem of the convergence in distribution of $S_n/\sqrt{n}$, we shall make some comments in the conclusion:

7 Conclusions

In this approach to determine the limiting distribution law of $\frac{S_n}{\sqrt{n}}$ we have sought to compute the asymptotic behavior of the moments of $\frac{S_n}{\sqrt{n}}$. If the parameter $\beta = \frac{\alpha}{4\pi}$ admits an expansion in bounded continued fraction, the behavior obtained for the expectation values of moments $E\left(\frac{S_n^{2k}}{n^k}\right) = \mathcal{O}(1) \leq A_k$ may lead to the convergence of the series $\sum_{k=0}^{\infty} \frac{(it)^{2k}}{2k!} A_k$, around $t = 0$. In that case, the sequence $\Phi_n(t)$ converges towards $\Phi(t)$, which is analytic near the origin. This implies the existence of a limiting distribution with finite moments. The estimation of the speed of the increase of the A_k seems difficult and is still an open problem. It is thus difficult to have an idea of the limiting distribution without such estimation, Although the procedure does not imply the convergence in distribution for $\frac{S_n}{\sqrt{n}}$, it shows that this normalization leading to bounded second moment, fails to lead to bounded moments of higher orders when β is an irrational having no expansion in bounded continued fractions.

Acknowledgments

It is a pleasure to thank Martine Queffelec for exchange of informations about works on Gaussian sums and continued fraction decomposition.
